$$r_{ij} = \begin{cases} 0.5 & a_i \text{ is different to } a_j \\ (0.5,1) & a_i \text{ is preferred than } a_j \\ 1 & a_i \text{ is absolutely preferred than } a_j \end{cases}$$

The preference matrix R is presumed to be additive reciprocal, $p_{ij} + p_{ji} = 1, \ \forall i, \ j \in \{1,...,n\}$. Several propositions are associated to the consistent additive preference relations as follows:

Proposition 1 [19]**:** *Consider a set of criteria or alternatives,* $X = \{x_1,..., x_n\}$*, and associated with a reciprocal multiplicative preference relation* $A = (a_{ij})$ *for* $a_{ij} \in \left[\frac{1}{9}, 9\right]$*. Then, the corresponding reciprocal fuzzy preference relation,* $P = (p_{ij})$ *with* $p_{ij} \in [0,1]$ *associated with A is given by the following formulation:*

$$p_{ij} = g(a_{ij}) = \frac{1}{2}(1 + \log_9 a_{ij}) \tag{7}$$

Generally, if $a_{ij} \in \left[\frac{1}{n}, n\right]$*, then* $\log_n a_{ij}$ *is used, in particular, when* $a_{ij} \in \left[\frac{1}{9}, 9\right]$*;* $\log_9 a_{ij}$ *is considered as in the above proposition because* a_{ij} is between $\frac{1}{9}$ *and 9. If* a_{ij} is between $\frac{1}{7}$ *and 7, then* $\log_7 a_{ij}$ *is used.*
.

Proposition 2 [19]**:** *For a reciprocal fuzzy preference relation* $P = (p_{ij})$ *, the following statements are* equivalent

(1) $p_{ij} + p_{jk} + p_{ki} = \frac{3}{2}, \ \forall i, j, k$ (8)

(2) $p_{ij} + p_{jk} + p_{ki} = \frac{3}{2}, \ \forall i < j < k$ (9)

Proposition 3 [19]**:** *For a reciprocal fuzzy preference relation* $P = (p_{ij})$ *, the following statements are equivalent:*

(1) $p_{ij} + p_{jk} + p_{ki} = \frac{3}{2}, \ \forall i < j < k$

(2) $p_{i(i+1)} + p_{(i+1)(i+2)} + ... + p_{(j-1)j} + p_{ji} = \frac{j - i + 1}{2}$, $\forall i < j$ (10)

Proposition 3 is crucial because it can be used to construct a consistent fuzzy preference relations form the set of $n-1$ values $\{p_{12}, p_{23},..., p_{n-1}\}$. A decision matrix with entries that are not in the interval $[0,1]$, but in an interval $[-c, 1+c]$, $c > 0$, can be obtained by transforming the obtained values using a transformation function that preserves reciprocity and additive consistency with the function:

$$f : [-c, 1+c] \to [0,1], \ f(x) = \frac{(x + c)}{(1 + 2c)} \tag{11}$$

Phase 2: Fuzzy Risk Assessment of Likelihood and Consequence

Stage 1: Assess the real risk matrix into z-numbers for likelihood, consequence and risk level.
Z-numbers are utilised in capturing knowledge of human being in term of consideration of reliability aspect.

Stage 2: Establish a risk matrix using z-numbers as depicted in Table 3 and Table 4, then convert into type-1 fuzzy sets.
Z-numbers are converted into type-1 fuzzy sets using Eq. (3).

Stage 3: Aggregate the results for likelihood and consequence process.
Aggregate the likelihood and consequence process using Eq. (6).
Stage 4: Compute the fuzzy risk assessment for likelihood and consequence process.
The fuzzy risk assessment, *FRA* process can be computed by equation as follows:

$$FRA = \frac{\sum_{k=1}^{n}\left(Likelihood_i \times Consequenc_i\right)}{\sum_{k=1}^{n}\left(Likelihood\right)} \quad (12)$$

The risk matrix shows in Figure 3 has been used to generate the likelihood, consequence and risk in the model. The risk matrix has been applied by oil and gas industry to evaluate the overall risk of hazard by qualitatively.

Table 3 Linguistic fuzzy scale of likelihood

Likelihood	Trapezoidal fuzzy numbers
Rare	(1,1,2,3;1)
Unlikely	(2,3,4,5;1)
Possible	(4,5,6,7;1)
Likely	(6,7,8,9;1)
Almost Certain	(8,9,10,10;1)

Consequence	Trapezoidal fuzzy numbers
Insignificant	(1,1,2,3;1)
Minor	(2,3,4,5;1)
Moderate	(4,5,6,7;1)
Major	(6,7,8,9;1)
Severe	(8,9,10,10;1)

Table 5 Linguistic fuzzy scale of risk level

Risk level	Trapezoidal fuzzy numbers
Low	(0,2,3,4;1)
Medium	(3,4,5,6;1)
High	(5,6,7,8;1)
Very high	(6,7,8,10;1)

	Consequence				
Likelihood	**Insignificant**	**Minor**	**Moderate**	**Major**	**Severe**
Almost Certain	Medium	High	High	Extreme	Extreme
Likely	Medium	Medium	High	Extreme	Extreme
Possible	Medium	Medium	High	High	Extreme
Unlikely	Low	Medium	Medium	High	High
Rare	Low	Low	Medium	High	High

Fig. 3: Risk assessment matrix

Stage 4: Rank the criteria evaluated according to risk vales.
Risk value can be referred to Table 5 and Figure 3.

Phase 3: Integrated Fuzzy Risk Scores

Integrated fuzzy risk scores, *IFRS* for risk assessment are computed in this phase using equation below:

$$IFRS = FW^{0.1} \times FRA \quad (13)$$

The final score is compulsorily in the range of $0 \le IFRS \le 10$. The value of IFRS capable to determine the scaling and assignment of risk levels (Table 5) that best suits its priorities and available resources. In addition, it capable to rank the criteria/ inputs related to knowledge of human being properly without losing the nature of fuzzy/ uncertain environment.

FUZZY RISK ASSESSMENT IN OIL AND GAS INDUSTRY

Mercury exposure hazard has been used as a case study. Mercury is a natural component of oil and gas, and may be present at high concentrations in some formations. When these gas reservoirs are produced and the processed fluids are cooled, liquid mercury can condense within heat exchangers, separators, coolers, valves, and piping. When this equipment (particularly components made from magnesium or aluminum alloys) is taken apart for maintenance or repair, workers can be exposed to mercury vapour. The risk analyst must conduct a hazardous materials survey and a risk assessment for mercury exposure during decontamination of turnaround in refinery plant. Risk analysts assessed individually the effects of mercury exposure as likelihood and consequence of four categories; personnel safety, environment, property damage, and reputation.

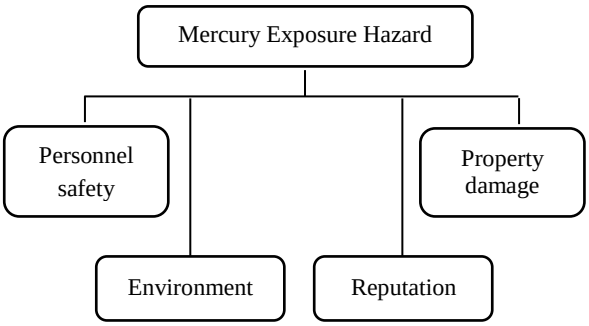

Fig. 4: Structure of risk assessment on mercury exposure hazard.

Phase 1: Fuzzy Weights Evaluation of Criteria
Table 6 depicts the fuzzy weight results for each criterion using the proposed reliability model. Personnel safety criterion depicts the highest weight value with 0.3299, followed by property damage with 0.2693, environment with 0.2279 and reputation with 0.1729. Based on risk analysts' evaluations, personnel safety , property damage and environment play important role in risk assessment in chemical hazardous.

Table 6 Fuzzy weight dimension results

Criteria	Reputation	Property Damage	Environment	Personnel Safety	Average	Weight	Rank
Reputation	0.5	0.3071	0.39	0.1858	0.3457	0.1729	4
Property Damage	0.6929	0.5	0.5829	0.3788	0.5387	0.2693	2
Environment	0.61	0.4171	0.5	0.2958	0.4557	0.2279	3
Personnel Safety	0.8142	0.6212	0.7042	0.5	0.6599	0.3299	1

Phase 2: Fuzzy Risk Assessment of Likelihood and Consequence
Table 7 depicts the evaluation of each criterion based consequence and likelihood assessment from three risk analysts with reliability assessment as well. Table 8 shows the risk assessment results and risk ranking of four criteria. It indicating the risk level of criterion personnel safety has the highest ranking with its value 8.341. However, the other criteria; property damage, environment, asset and reputation have the least priority as compared to personnel safety.

Table 8 Risk assessment results of each criterion based on likelihood and consequence

Criteria	Risk level	Rank
Personnel Safety	8.341	1
Environment	7.131	3
Property Damage	8.175	2
Reputation	6.022	4

Table 7 Risk assessment of likelihood and consequence process

Criteria	Risk Analyst 1		Risk Analyst 2		Risk Analyst 3	
	Consequence	Likelihood	Consequence	Likelihood	Consequence	Likelihood
Personnel Safety	5 (VH)	5 (VH)	5 (H)	5 (H)	4 (VH)	4 (VH)
Environment	4 (VH)	4 (VH)	4 (H)	4 (H)	4 (VH)	4 (VH)
Property Damage	4 (VH)	4 (VH)	5 (VH)	3 (VH)	5 (H)	4 (H)
Reputation	4 (VH)	3 (VH)	3 (VH)	3 (VH)	3 (VH)	4 (VH)

Phase 3: Integrated Fuzzy Risk Scores

Table 8 Integrated fuzzy risk scores between fuzzy weight and fuzzy risk level.

Criteria	Integrated fuzzy risk score (IFRS)	Rank
Personnel Safety	7.4658	1
Environment	6.1506	3
Property Damage	7.1702	2
Reputation	5.0529	4

Aforementioned in Section 3, the final score/ IFRS of risk assessment is the integration of two different methodologies which are from phase 1 and phase 2. The value of IFRS has capability to double check the ranking evaluated in earlier phase. The final ranking depicts personnel safety as the highest rank, followed by property damage, environment and reputation.

CONCLUSION

This study introduces the integrated fuzy risk assessment using consistent fuzzy preference relations and fuzzy risk assessment using z-numbers. In dealing with the uncertainty and complexity in the information, the reliability of information is taken into consideration efficiently. Z-numbers have better capability in describing uncertain and complex knowledge. For this reason, z-numbers are used in this work. The proposed methodology is developed by improvising several steps in computing the consistent fuzzy preference relations and fuzzy risk assessment using z-numbers to make sure both methodologies are well integrated. The proposed

model is capable of interacting or cooperating with unlimited criteria in dealing with real world decision making problems.

The proposed fuzzy risk assessment in human based decision making by capturing uncertainty in human judgement. Due to access information and availability of the incomplete and uncertain data, it is hard to make a right decision. In this sense, it is important to modify some classical techniques and models by adding intuitive reasoning and human subjectivity. As compared with the existing risk ranking method, the proposed fuzzy risk assessment is able to provide the risk level score more precisely and accurately and will also assist to reduce the risk ranking ties wherever possible and it can integrate the opinions of experts in a more accurate way and can rank the risk levels quantitatively. As a consequence, the proposed fuzzy risk assessment offers a robust and reliable methodology that provides best assessment with regard to available resources. Therefore, this methodology can be further extended in order by considering complicated case studies drawn from a wide range of human based decision making problems.

LEAD IMMOBILIZATION IN ARTIFICIAL CONTAMINATED SOIL USING SULFUR-IMPREGNATED CARBONACEOUS BAMBOO

Takaaki Wajima[1]
[1]Department of Urban Environment Systems, Chiba University, Japan

ABSTRACT

A novel carbonaceous immobilizing agent for heavy metal contaminated soil was prepared from bamboo using sulfur immersion and pyrolysis, and the lead immobilization in artificial contaminated soils using sulfur-impregnated carbonaceous material was estimated. The bamboo was powdered, dried, and then immersed in 0.1 - 1 M K_2S solution for 0 - 24 h to prepare sulfur-immersed materials. The immersed-materials were heated at 400 ^oC for 1 h in nitrogen gas to produce the sulfur-impregnated carbonaceous material by pyrolysis. The abilities of the product to immobilize lead from aqueous solution were examined to obtain the product with high lead immobilization ability. With increasing K_2S concentration, the immobilization ability of the product for lead gradually increases and then above 0.75 M K_2S those are almost constant, while 15 min is sufficient for the immersed time to obtain the product with high lead immobilization ability. The product prepared from material immersed in more than 0.75 M K_2S solution for more than 15 min has a maximum immobilization ability for lead ion of 2.78 mg/g. The lead immobilization using the sulfur-impregnated product is sustainable due to the formation of leadhillite [$Pb_4SO_4(CO_3)_2(OH)_2$] and lead carbonate [$Pb(CO_3)_2O$]. The product can immobilize lead ion in various artificial lead contaminated soils. By mixing artificial lead contaminated soil with the sulfur-impregnated product, the eluted solution became neutral, and the eluted concentrations of lead ion dropped below the Japanese elution standard for soil.

Keywords: Sulfur-impregnation, Lead immobilization, Bamboo, Artificial contaminated soil, Pyrolysis

INTRODUCTION

Soil contamination with heavy metals is a worldwide problem. Accumulation of heavy metals in soils affect soil ecology, agricultural productivity, quality of agricultural products, water resources, and serious health problems for human and animal [1]. In the United States, for example, approximately 63 % of the sites on the National Priority List (NPL) for the treatment of contaminated soils are contaminated by metals, and lead is the most common metal, found at 15 % of the sites. In Japan, according to a report by the Ministry of Environment, 43 % of the contaminated sites that exceed the environmental quality standards are contaminated by lead compounds. Soil contamination by lead compounds is also prevalent in other developed and developing countries where lead compounds are used extensively in industrial activities without careful contamination management.

Lead is a ubiquitous heavy metal pollutant in soils due to their use widely. The primary sources of Pb contamination include industrial activities such as mining, smelting of metals, and the use of Pb-containing products such as paints, lead-acid batteries, bullets, gasoline and pesticides [2]. It can damage human nervous (especially children) and reproductive systems [3]. The high concentration of Pb in the soil poses risks to human and animal health by the leaching of metals from the soil into water and the consumption of edible plants growth in the contaminated soil. Therefore, proper remediation is necessary to reduce metal availability in soil for protecting human health.

Among available remediation technologies, in situ immobilization of heavy metals using a chemical amendment can be a cost-effective and environmentally sustainable remediation approach for the immobilization of heavy metals by reducing the mobility and availability. This immobilization technique may provide a long-term remediation solution if low solubility minerals and/or stable precipitates are produced in situ [4]. Therefore, the choice of the soil amendments need that the amendments must reduce heavy metals transfers from contaminated soils to the surface water or groundwater and uptake by plants and organism. The most common agents for lead immobilization are phosphate-based compounds [5-7]. Although these studies have successfully demonstrated that phosphates effectively immobilize lead in various contaminated soils, there are several concerns about the use of phosphate as agents for lead immobilization. First, from an environmental protection point of view, excessive supplied phosphate can lead to eutrophication in the natural environment. Second, from a resource conservation point of view, phosphate is becoming a precious element, especially in countries such as Japan that import a major portion of their phosphate

requirements. For these reasons, research on other types of lead immobilization agents is needed. Soil amendments, lime [8], calcium carbonate [9], red-mud [10], fly ash [11] and so on, may decrease leachable concentrations of contaminants and thus reduce the detrimental effects of heavy metals on environmental receptors, such as microorganisms, plants, animals, water and humans [12].

In previous studies, sulfur-impregnated adsorbents with high removal abilities for heavy metals were prepared from paper sludge, cedar bark and rice husk using K_2S solution [13-15]. According to the Pearson theory, the sulfur, as a soft base, should interact with heavy metals such as Zn^{2+}, Pb^{2+}, Cd^{2+} and Ni^{2+} (soft acids) rather than with oxygen (a hard base) in the activated carbon. From these results, it would be possible to produce a low cost agent to immobilize the metal ions in contaminated soils from agricultural waste.

Bamboo is a renewable bioresource and abundantly found in different geographic areas of the world. Bamboos, fast growing plants, are natural composite materials useful in construction, textile industry and so on. Large quantities of bamboo waste are generated every year, which could be a biomass feed stock for char production due to its high fraction of lignocelluloses [16]. Bamboo charcoal is one of the promising adsorbents enriched with microporous structure and higher surface area. The surface area of bamboo charcoal is generally 3-10 times higher than compared to the world charcoal. The surface porous structure and heterogeneity of charcoal materials can be improved by modification process which has significant effects on adsorption performance. The physical and chemical modification of bamboo charcoal can enhance its affinity to adsorbate ions which is evidenced by earlier studies [17]. In recent years, very few studies have been conducted for adsorption of heavy metals using bamboo charcoal [18, 19].

From these background, in this study, we attempted to prepare the lead immobilization agent from bamboo using sulfur-impregnation, and lead immobilization ability of the sulfur-impregnated product was estimated using artificial lead contaminated soils.

MATERIALS AND METHODS

Raw Sample

Bamboo, which was collected from a forest area in Chiba prefecture, Japan, first pulverize under 3 mm length, then washed with distilled water, and dried and stored for use. Properties of bamboo sample are shown in Table 1, and mineralogical composition of bamboo is shown in Fig. 1, which indicates that bamboo mainly composed of cellulose. All reagents were purchased from Wako Chemical Co., Japan at analytical grade.

Table 1 Properties of bamboo sample

Moisture	Ash	Fixed carbon and Volatile matter		
		C	H	N
11 %	2 %	44.9 %	5.4 %	0.2 %

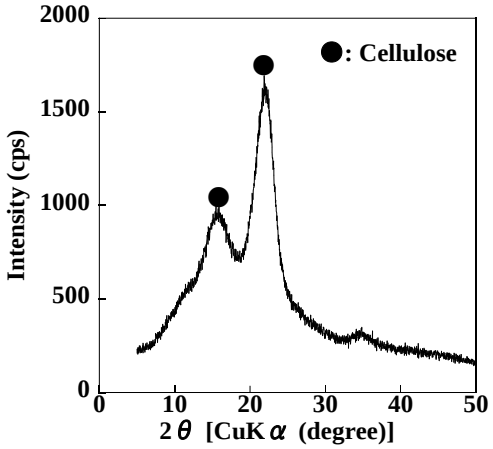

Fig. 1 XRD patterns of bamboo.

Sulfur Impregnation

20 g of sample was immersed in 200 mL of 0.1 - 1 M K_2S solution for 0 - 24 h, then filtered, and dried in a drying oven overnight to obtain sulfur-immersed samples. These samples were pyrolyzed using a horizontal reactor. Sulfur-immersed samples were put in a ceramic board, and installed in a transparent quartz tube of 0.45 mm inside diameter and 1 m in length. Before pyrolysis, N_2 gas was injected into the tube for 30 min at a rate of 1.0 L/min to replace the air in the tube. The board was heated in an electric furnace at 400 ^oC for 1 h, with a continuous flow of N_2 gas at a rate of 1.0 L/min. After heating, the solid was cooled to room temperature with a steady N_2 gas flow (1.0 L/min) in the tube, then washed with distilled water and dried in drying oven overnight to obtain the sulfur-impregnated material.

The abilities of the material for immobilization of lead ion from aqueous solution were examined as follows. 0.1 g of the sample was added to 10 mL of $Pb(NO_3)_2$ solution with 10 mM in 50 mL centrifuged tube, and was shaken in a reciprocal shaker for 24 h. After shaking, the slurry was centrifuged, and the pH of the supernatant and the concentration of Pb^{2+} in the supernatant were measured by pH meter (D-53, Horiba) and atomic absorption spectrophotometer (AAS) (AAnalyst200, PerkinElmer), respectively. The immobilization ratios of Pb^{2+} were calculated using the following equation:

$$R = \frac{(C_0 - C_e)}{C_0} \times 100 \quad (1)$$

Here, R = Immobilization ratio of Pb^{2+} (%), C_0 = Initial concentration of Pb^{2+} in the solution (mg/L), and C_e = Measure concentration of Pb^{2+} in the solution (mg/L).

After lead immobilization, each sample (1.0 g) was added into 10 mL of distilled water in 50 mL of centrifuged tube, and tube was shaken for 6 h. After shaking, the slurry was centrifuged, and the concentration of Pb^{2+} in the supernatant was measured by AAS to calculate the elution of lead

The samples were analyzed by powder X-ray diffraction (XRD) with monochromate CuKα radiation (Ultima IV, Rigaku).

Lead Immobilization

Four soil samples, Akadama soil, Kanuma soil, black soil and river sand, were used to prepare artificially lead-contaminated soils. Lead-contaminated soil was artificially prepared by mixing 30 g of soil sample and 300 mL of 1000 mg-Pb/L aqueous solution (provided by $Pb(NO_3)_2$) using a rotary stirrer for 6 h. After mixing, the mixture stands at room temperature for 7 days, and then filtrate. The concentration of Pb^{2+} in the filtrate was measured by AAS to calculate the content of lead in artificially contaminated soils. The solid was dried in air for 7 days to obtain artificially contaminated soil.

1 g of artificially contaminated soil without or with 0.01 – 0.1 g of sulfur-impregnated product was added into 50 mL of a conical flask, and 10 mL of distilled water was then poured. The flask was shaken with shaking incubator at 50 °C for 6 h, and then filtrate. The pH of the filtrate was measured by pH meter, and the eluted concentration of Pb^{2+} in the filtrate is measured by AAS.

RESULTS AND DISCUSSION

Lead Immobilization of Sulfur-Impregnated Product

Figure 2 shows the lead immobilization of the product from bamboo via pyrolysis of the bamboo immersed in 0.5 mol/L K_2S solution for various times, and pH of the solution after lead immobilization. With increasing immersion time, lead immobilization of the product rapidly increases, and then be almost constant (about 55 %) after 15 min. It is noted that pH of the solution is almost 5.2 after addition of the product.

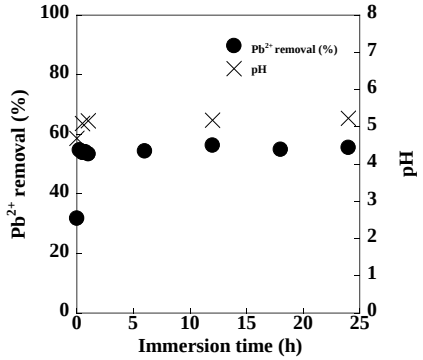

Fig. 2 Lead immobilization of the product from bamboo via pyrolysis of the bamboo immersed in 0.5 mol/L K_2S solution for various times, and pH of the solution after lead immobilization.

Figure 3 shows the lead immobilization of the product from bamboo via pyrolysis of the bamboo immersed in K_2S solution with various concentrations, and pH of the solution after lead immobilization. With increasing K_2S concertation to 0.75 mol/L, lead immobilization of the product increases, and be almost constant (approximately 80 %) above 0.75 mol/L K_2S solution, which is more than 2 times higher than the product without sulfur-impregnation. It is noted that pH of the solution after lead immobilization of the product with sulfur-impregnation is 5.0 - 5.5, which is higher than that without sulfur-impregnation (4.8).

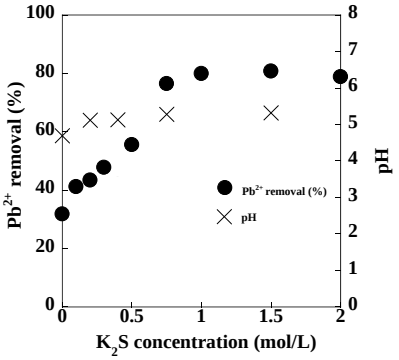

Fig. 3 Lead immobilization of the product from bamboo via pyrolysis of the bamboo immersed in K_2S solution with various concentrations, and pH of the solution after lead immobilization.

Figure 4 shows the XRD patterns of (a) immersed bamboo and (b) the products from bamboo via pyrolysis of the bamboo immersed in 0.5 mol/L K_2S solution for various times, and Figure 5 shows the XRD patterns of (a) immersed bamboo and (b) the products from bamboo via pyrolysis of the bamboo immersed in K_2S solution with various concentrations. Regardless of the immersed conditions, the bamboo after K_2S immersion have cellulose peaks, which is almost same as raw bamboo (Fig. 4 (a), Fig. 5 (a)). After pyrolysis, the pyrolyzed bamboo products have amorphous structure (Fig. 4 (b), Fig. 5 (b)).

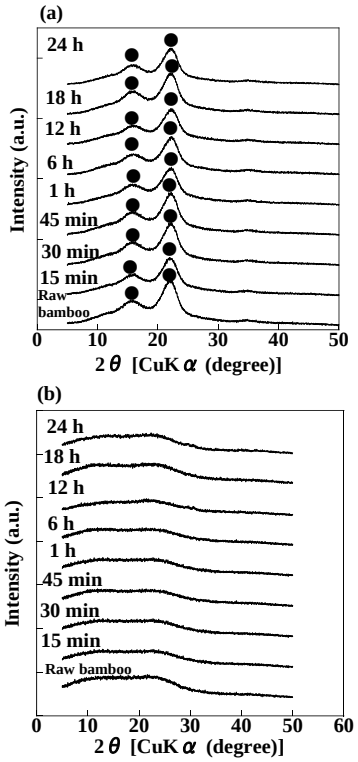

Fig. 4 XRD patterns of (a) immersed bamboo and (b) the products from bamboo via pyrolysis of the bamboo immersed in 0.5 mol/L K_2S solution for various times.

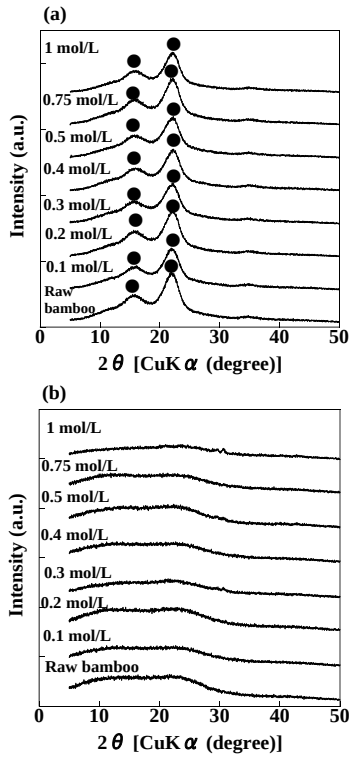

Fig. 5 XRD patterns of (a) immersed bamboo and (b) the products from bamboo via pyrolysis of the bamboo immersed in K_2S solution with various concentrations.

Figure 6 shows the XRD patterns of the products after lead immobilization test using (a) the products from bamboo via pyrolysis of the bamboo immersed in 0.5 mol/L K_2S solution for various times and (b) the products from bamboo via pyrolysis of the bamboo immersed in K_2S solution with various concentrations. After lead immobilization test, while lead carbonate [$Pb(CO_3)_2O$] appears in the product without sulfur-impregnation, lead carbonate and leadhilite [$Pb_4SO_4(CO_3)_2(OH)_2$] appear in the product with sulfur-impregnation, which means that sulfur-impregnated product has higher lead removal ability than the product without sulfur-impregnation, due to the formation of leadhilite by sulfur content in the product.

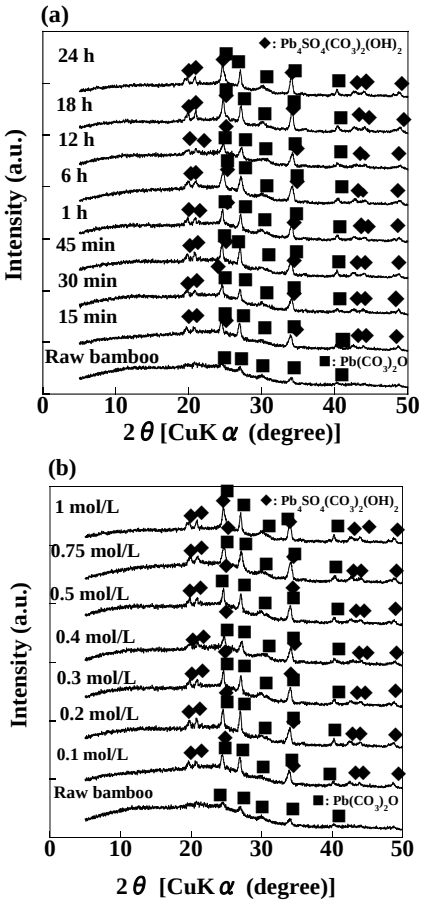

Fig. 6 XRD patterns of the products after lead immobilization test using (a) the products from bamboo via pyrolysis of the bamboo immersed in 0.5 mol/L K_2S solution for various times and (b) the products from bamboo via pyrolysis of the bamboo immersed in K_2S solution with various concentrations.

From these results, lead immobilization agent can be prepared from bamboo via pyrolysis of the bamboo immersed in higher than 0.75 mol/L K_2S solution for more than 15 min, indicating a maximum immobilization ability for lead ion of 2.78 mg/g.

Figure 7 shows the lead elution from the products from bamboo via pyrolysis of the bamboo immersed in K_2S solution with various concentrations. Lead elution from the product without sulfur impregnation is 35 %, while that of the product with sulfur-impregnation is zero, which means that the sulfur-impregnated product can strongly immobilize lead in the product.

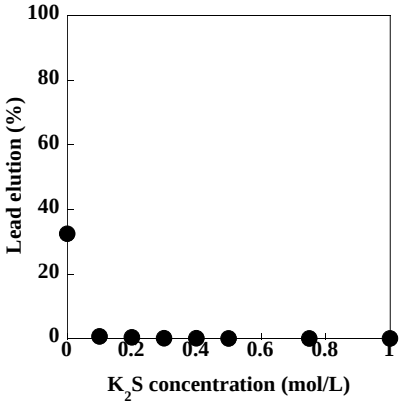

Fig. 7 Lead elution from the products from bamboo via pyrolysis of the bamboo immersed in K_2S solution with various concentrations.

Lead Immobilization

The lead immobilization of the obtained product was examined using artificial contaminated soils. It is noted that the lead content of artificial contaminated soils used in this experiment is black soil (9799 mg/kg) > akadama soil (8347 mg/kg) > kanuma soil (6969 mg/kg) > river sand (4185 mg/kg).

Figure 8 shows the pH of the solution and the eluted lead concentrations after elution test using artificial contaminated soils with addition of sulfur-impregnated product. Without addition of the product, pH of the solution is weak acidic (pH 4-6), and with increasing addition of the product, pH of the solution increased. With addition of 0.1 g product, pHs of the solution using akadama soil, kanuma soil and black soil are neutral, while that using river sand is weak alkaline. It is considered that the product is alkaline material and three soils have pH buffering ability.

Without addition of the product, high concentrations of lead were eluted from kanuma soil (85.5 mg/L) and akadama soil (63.5 mg/L), while elution from black soil (1.0 mg/L) and river sand (1.1 mg/L) are low. With increasing addition of the product, the lead elution decreases, and with addition of 0.1 g product, the lead elution from all samples are not detected using AAS. It is noted that Japanese standard of soil elution is less than 0.01 mg/L. It would be considered that the product can immobilized lead ion in various soils.

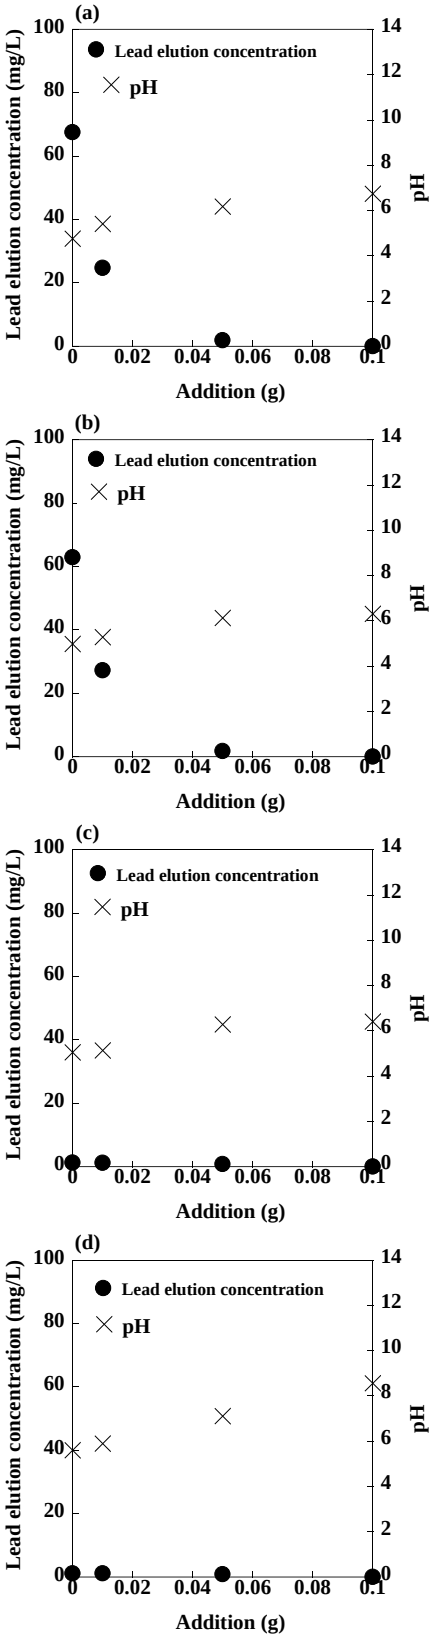

Fig. 8 The pH of the solution and the eluted lead concentrations after elution test using artificial contaminated soils with addition of sulfur-impregnated product: (a) Akadama soil, (b) Kanuma soil, (c) Black soil, and (d) River sand.

From these results, it would be possible that, by mixing lead contaminated soil with sulfur-impregnated product, the eluted solution becomes neutral and the concentration of lead drops below the Japanese eluted standard for soil.

CONCLUSIONS

A novel carbonaceous immobilizing agent for heavy metal contaminated soil can be prepared from rice straw using sulfur immersion and pyrolysis, and can immobilize lead ion in various artificial lead contaminated soils.

[2] Faculty of Engineering, Chiang Mai University, Thailand

ABSTRACT

Transport demand is one of the essential datasets for urban / transport planning and policy development. However, the full size of travel demand survey requires large amount of cost, therefore the survey is merely conducted in developing countries. Their policy decision might be based on the old and limited datasets. In this study we propose a new approach to estimate transport demand using the night-time light satellite image based on the correlation of these two factors. Taking the case of Chiang Mai Metropolitan area, we found a soft relationship between the night-time light intensity and trip generation/trip attraction. Transport survey data is provided by Chiang Mai University for the year 2016. NOAA provides cloud free monthly composite of night-time light satellite image (VIIRS-DNB) by Suomi-NPP satellite of which resolution is 15 arc-second (about 500m by 500m at equator). It is spatially more precise than zones of travel demand survey and monthly frequency. Applying the relationship between transport demand and night-time light intensity, we propose a method to update the transport demand with higher spatial resolution.

Keywords: Transport demand update, Night-time light satellite image

INTRODUCTION

Current and future transportation demand are essential information for urban / transport planning and policy development. As input for transport demand analysis like traditional four step models [1] massive number of samples are required in travel survey to achieve enough accurate demand modeling to apply in policy and planning practice. They were often as big as 1-3% of the population [2]. This big sample size requires huge budget for the survey, therefore the frequency of the full-size survey is quite low even in the developed countries. Recently tracking devices like GPS and smart phone are found to have enough performance for accurate and low-cost travel survey [3], however the data privacy issue limits the use of those data in public policy.

In developing countries, the urbanization is rapidly progressing, that induces increase and expansion of urban activities including travel and land development [4]. That requires frequent monitoring of urban activities however the full-size survey is merely conducted due to its high cost.

Meanwhile several studies indicate night-time light satellite images can represent economic activities of a region [5-7]. Especially, the Visible Infrared Imaging Radiometer Suite (VIIRS) sensor on the Suomi National Polar-orbiting Partnership (NPP) Satellite [8-12] provides a Day-Night Band (DNB) in which nighttime light is observed and it has higher performance in detecting the radiation range comparing the Defense Meteorological Satellite Program's Operational Line-scan System (DMSP-OLS) that enables to detect the light intensity within cities.

Travels are also induced by economic activities, so the night-time light image could be a cue to estimate the transport demand. For the VIIRS-DNB, National Oceanic and Atmospheric Administration (NOAA) provides monthly composite of cloud free images since April, 2012. This update frequency is enough high to capture the urban dynamics in developing countries. If this night-time light information can be applicable in updating the travel demand, it will be a very powerful tool in urban and transportation planning in developing countries.

In this study, we examine the applicability of VIIRS-DNB in travel demand update taking the case of Chiang Mai, Thailand. We focus on the zonal trip generation and attraction and try to explain the travel demand by night-time light intensity statistically. Based on this statistical relationship, we attempt to update the trip generation and attraction using the updated night-time light image.

DATA

In this study, we examine the relationship between trip generation / attraction and night-time light. Chiang Mai household travel survey data in 2016 is used as data for travel demand, and monthly composite of Suomi-NPP VIIRS DNB in January 2016 is used as night-time light data.

Chiang Mai household travel survey was

conducted by Department of Civil Engineering, Chiang Mai University in February 2016 in which 6,236 households were visited and travel information of household members from 6 years old and above were collected. This is equivalent to an overall sample size of 3.4%. The survey area comprises of Chiang Mai Metropolitan and surrounding sub-district municipalities. Its total area is 1,606.35 sq.km. This area is divided into 142 zones. The population of target region is 761,986 in 2016. The population trip generation and attraction were estimated by expanding that of zonal sample statistic by zonal sample size expansion factor. The estimated trip generation per zone area for each zone is shown in Fig.1. The number is standardized by area because the area is different by zones. The estimated total number of trip generation / attraction is 3.6 million per day. The correlation between zonal trip generation and attraction per day is 0.95 and they have quite similar figure of spatial distribution.

The monthly composite of Suomi-NPP VIIRS DNB in January 2016 is obtained from NOAA website. We choose the image for January because it is dry season and effect of cloud on the observation is smaller than that in the months of rainy season. The projection is WGS84 latitude-longitude coordinate system, resolution of the image is 15 arc-second and the unit of the light intensity is given in nanoWatts/cm2/sr. The data overlaid with travel survey zone system is shown in Fig. 2.

Comparing the figures of spatial distribution of trip generation and night-time light, the volume and the intensity looks to have similar pattern. Fig. 3 shows the relationship between trip generation per area (horizontal axis) and average night-time light intensity (vertical axis) of each zone. A positive relationship between the night-time light and trip generation can be found in this figure. Based on this fact, we investigate the relationship between these two factors using simple non-linear model in the next section.

MODEL AND PARAMETER ESTIMATION

We assume that trips are generated/attracted only at meshes where the night-time light is more than zero and it is also assumed that the trip volume is larger as higher the level of night-time light radiation. With this assumption, we presume the following model for trip generation/attraction.

$$\frac{q_j}{a_j} = \alpha_0 l_j^{\alpha_1} \qquad (1)$$

Where q_j is trip generation or attraction at mesh j, a_j is area of mesh j, l_j is night-time intensity at mesh j, and α_0, α_1 are parameters. Here trip generation data for each mesh is not obtained, but that for the zonal data is obtained. So above equation is aggregated by zonal level.

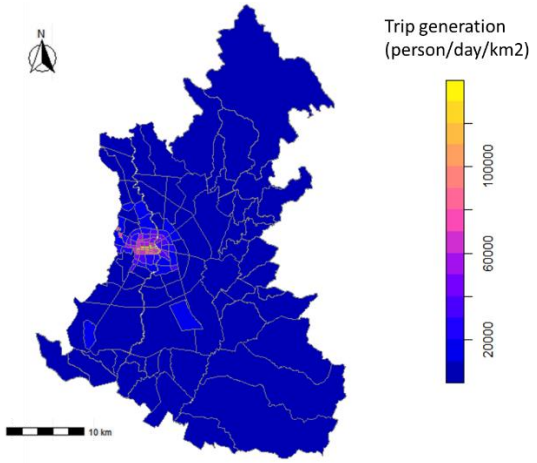

Fig.1 Spatial distribution of trip generation

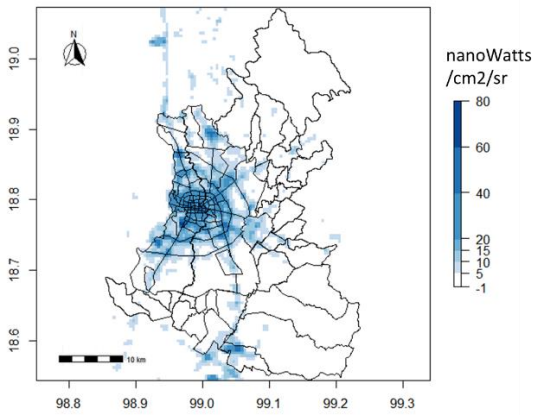

Fig.2 Night-time light intensity

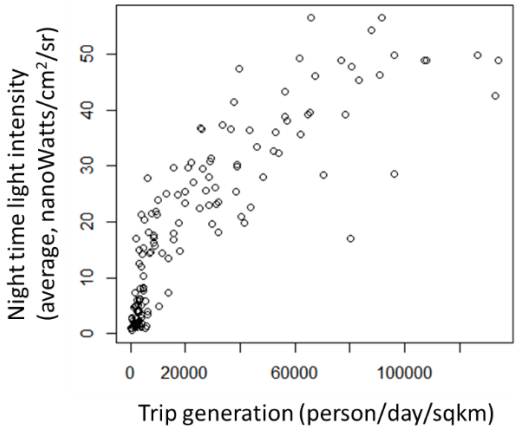

Fig.3 Relationship between trip generation and night-time light intensity

$$\frac{Q_i}{A_i} = \alpha_0 \frac{\sum_{j\in\Omega_i} l_j^{\alpha_1} a_j}{\sum_{j\in\Omega_i} a_j} = \frac{\alpha_0}{|\Omega_i|} \sum_{j\in\Omega_i} l_j^{\alpha_1} \qquad (2)$$

Where Ω_i is set of mesh whose night-time light intensity is more than zero in zone i, Q_i and A_i are trip

generation/attraction and mesh area where night-time light intensity is more than zero in zone *i* respectively. The last term assumes area of all mesh is identical and $|\Omega_i|$ represents the number of mesh. Here Q_i is obtained from travel survey, A_i and l_j can be derived from VIIRS-DNB datasets.

The parameters are estimated by solving the following problem.

$$\min_{\alpha_0,\alpha_1}\left(Q_i/A_i - \frac{\alpha_0}{|\Omega_i|}\sum_{j\in\Omega_i} l_j^{\alpha_1} \right)^2 \quad (3)$$

If we assume that the error term follows normal distribution, the above equation is variable part of log-likelihood function by α_0, α_1. This means the estimated parameters are maximum likelihood estimators. The statistics of estimated model is shown in Table 1. R^2 denotes the R squared of observed and estimated trip per area. Fig. 4 shows the relationship between observed and estimated trip generation. The trip attraction has quite similar figure with trip generation.

Table 1 Estimated parameters

	Trip generation		Trip attraction	
	parameter	t-value	parameter	t-value
α_0	12.73	3.45	183.5	2.94
α_1	2.28	30.29	1.58	17.42
R^2	0.70		0.74	

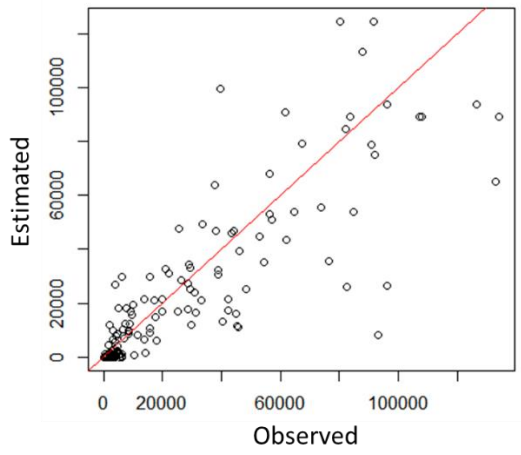

Fig.4 Plot of observed and estimated trip generation (trips/sq.km/day)

The parameter α1 is positive and more than unity. This means as stronger the intensity of night-time light larger trips is generated/attracted. It reflects the relationship between the night-time light and trip generation as shown in Fig.3. Its t-value is enough high so this parameter is statistically significant. The representability of the model is not satisfactory. Obviously, trip generation is affected by various factors, including population, floor area of buildings, land use, and the other urban activities, and it is not necessarily determined by night-time light solely. However, this result indicate that the night-time light can represent a certain part of urban activities and also have the correlation with trip generation and attraction.

Purpose of this study is to investigate a method to update the travel demand without huge survey. The statistical significance of estimated parameter indicates the night-time light image can be a clue for the travel demand update in dynamically growing cities in developing countries.

ESTIMATION OF FINER RESOLUTION OF TRAVEL DEMAND

The relationship between the night-time light and travel demand would suggest the possibility of travel demand estimation in finer spatial resolution especially in suburban zones. The zone system in this transport survey, the average size of a zone is 8.4km^2 and the largest size is 158km^2. For transport policy practice, it is desirable to capture the travel demand in finer spatial scale when the demand drastically change because it affect first local traffic situation and not zone wide situation.

It would be possible to estimate the travel demand using equation (1), however Fig.4 suggests there are substantial errors in the estimation. Here we introduce following adjustment factor β_i for zone *i* to make the estimation fit to the zonal observation of traffic demand.

$$\beta_i = \frac{Q_i}{A_i} \Big/ \frac{\alpha_0}{|\Omega_i|}\sum_{j\in\Omega_i} l_j^{\alpha_1} \quad (2)$$

The numerator is observed travel demand and the denominator is zonal sum of estimated demand by mesh level night-time light. Fig.5 shows the adjustment factor level of each zone on the map. This figure shows that the adjustment factor looks higher value at outer zones in the region. That would suggest the error might have relationship with the development level which may have correlation with the night-time light intensity. Fig.6 shows the relationship between zonal average of night-time light intensity (horizontal axis) and the adjustment factor (vertical axis) in logarithm scale for both axes.

From this figure, there is a tendency that the average night-time light is weaker the adjustment factor is larger. In addition, the adjustment factor tends to distribute around one when the night-time light intensity is enough high. So it would be suggested that the adjustment factor should not be fixed in lower night-time light zones. In this study we

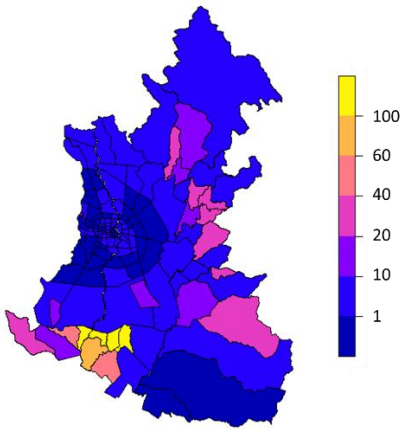

Fig.5 Adjustment factor of travel demand

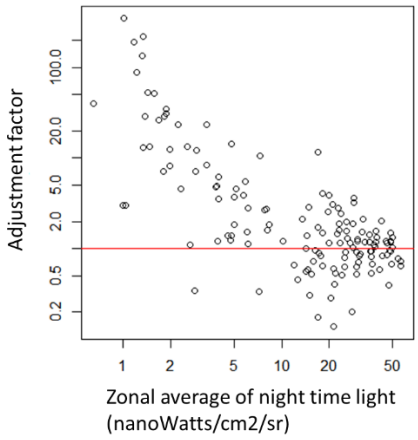

Fig.6 Night-time light and adjustment factor

do now examine the relationship further, but for future study, at the weaker night-time light like less than 10 nanoWatts/cm^2/sr it should be modified as night-time light getting to be stronger.

The estimated mesh level trip generation maps with and without adjustment are shown in Fig.7 and 8 respectively. The estimated trip generation with adjustment (Fig.7) indicates that trips are generated at Chiang Mai city center as well as along the corridors of major radius and circular roads. That is consistent with the experience in the target city where the major economic activities are located on those places.

Without adjustment (Fig.8), trip generation in suburban area is clearly underestimated and some nodes looks over estimated compare with the adjusted estimation. This result indicates that night-time light solely does not have enough performance to estimate the travel demand and the combination with the other appropriate information is required.

TRAVEL DEMAND UPDATE

Taking the case of Chiang Mai Metropolitan area, we found loose relationship between trip generation

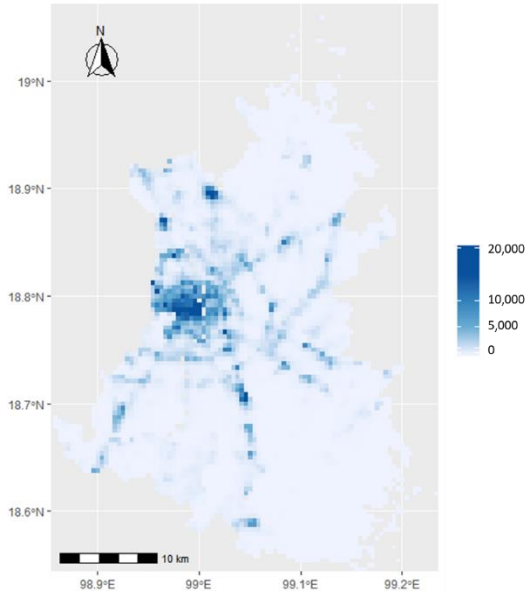

Fig.7 Estimated trip generation (adjusted)

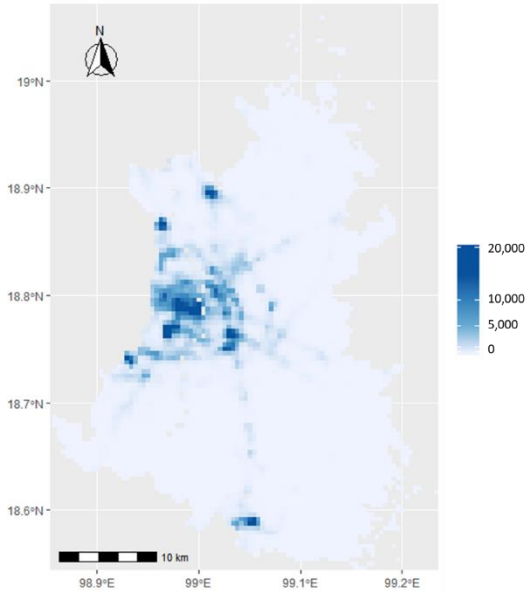

Fig.8 Estimated trip generation (non-adjusted)

/attraction and night-time light observed by VIIRS-DNB. This result indicates possibility of the travel demand update using the updated night-time light observation. In this section, we attempt to update the travel demand using the newly observed night-time light image.

Fig. 9 shows the histogram of the difference of night-time light intensity in target region between January 2016 and February 2019. The difference ranges -28 ~ +29 nanoWatts/cm^2/sr. This figure indicates that the most of the grids has almost the same intensity between the periods, but the distribution shifts towards brighter direction. The average of the change of nigh time light in the target

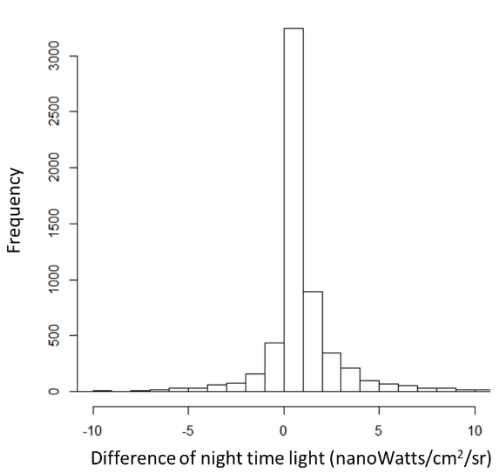

Fig.9 Difference of night-time light between January 2016 and February 2019

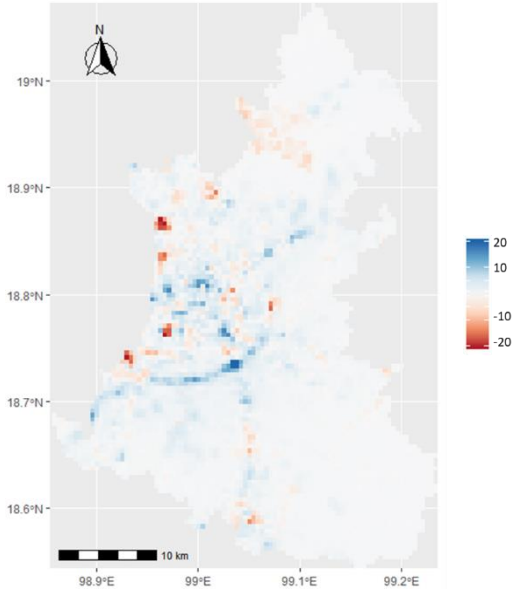

Fig.10 Spatial distribution of night-time light change between January 2016 and February 2019

region is 0.82 nanoWatts/cm^2/sr and the standard deviation is 2.49 nanoWatts/cm^2/sr.

The spatial distribution of night-time light change between 2016 and 2019 is shown in Fig. 10. It is noted that night-time light has gotten darker particularly at the east of target area. One site is at the north near the crossing point of Chiang Mai Outer Ring Road and Chotana Road, and the other place is Chiang Mai International Airport. Military facilities are located near these sites therefore the night-time light would occasionally change without reflecting the civil urban activities.

On the other hand, night-time light intensity has increased at two specific sites. One is at the center north of Chiang Mai city. This could reflect to the service expansion of a major provincial hospital at center north. The other is at the south part of the Outer Ring Road especially its crossing point with Chiang Mai-Lampang Highway. Alongside the south part of the Outer Ring Road, residential estates and commercial development resulting from the road being widen to 4 and 6 lanes has also been observed. This would be a factor on the night-time light change.

Applying the updated night-time light to equation (1), the updated traffic volume is estimated. The trip generation and attraction are estimated to increase 14% and 16%, respectively during this period. Compare with the total night-time light which is increased 18%, the travel demand increase is estimated to be moderate due to the non-linear relationship between the night-time light and travel demand. It is difficult to examine quantitatively due to lack of data, empirically the road traffic situation is getting severe with higher concentration of vehicle traffic recently. The method proposed in this paper can be provide a clue to investigate the updated spatial distribution of traffic demand.

DISCUSSION AND RECOMMENDATION

In this study, we attempt to examine the relationship between night-time light observed by satellite and trip generation in Chiang Mai Metropolitan Region 2016. We found that these two factors have non-linear positive relationship and estimated a model to calculate the travel demand from night-time light intensity. Based on the estimated model, we demonstrated the estimation of travel demand in finer spatial resolution compare to the ordinaly zone system. Additionally we applied this model to update the travel demand 2019. As a result, the total travel demand is estimated to increase about 15% from 2016. Looking at the spatial distribution of night-time light change, north city center and south part of outer ring road are the place where the travel demand is expected to increase significantly.

The proposed appraoch would be useful especially in developing cities where the temporal transport and economic statistics and surveys are limited at the same time the urban activities are growing and spatially shifting rapidly. The satellite image employed here is published periodically which can be a clue to capture the progress of urban and transprot situation and updating the urban and transport policy and planning.

CONCLUSION

In this study we proposed a new method to estimate the travel demand from night time light satellite image which is periodically published and distributed through the internet. The method was examined taking the case of transport demand estimation in Chiang Mai Thailand. We found a

cetrain level of representability of the transport demand observation and demonstrated the applicatiblity to a developing city.

The results in this study can be supported empirically however still need further examination to check its accuracy and reliability, and we also need further upgrading the method incorporating with the other data sources.

First, the estimation error shown in Fig. 4 is not neglegible as a projection model of travel demand. In this study we just employed adjustment factor to fit with the observed travel demand, but of course upgrade the model incorporating the other explanatory variable is desired. Sometimes population or floor area of buildings are employed as explanatory variables, however those input statistics are not surveyed frequently. It would be needed to explore the other information including open location data like Open street map and google place.

Second, further examination of the satellite image is needed. In this study we only utilize the image taken in January 2016 and February 2019. The VIIRS-DNB lose its accuracy by cloud cover because it observes visible light. Therefore the accuarcy of rainy season, for example July in Chiang Mai, is extremely low. However the images taken in the other dry month will also support the analysis. Of course another periodical satellite image products would support the analysis, but at this moment, the VIIRS-DNB is the most convenient periodical product for the urban activity analysis.

Finally, we need to investigate methods for travel survey. The data utilized in this study is relatively small sample survey and is expected to have substantial error especially in the peripheral zones in the target area. It would have induced analytical errors in this study. Travel survey methods using positioning device like smart phone and traffic counts survey are expected to improve the travel data quality.

NITROGEN SULFIDE AND BOD REDUCTION OF DOMESTIC WASTEWATER USING AQUATIC PLANTS

Thitinun Pongnam[1] and Chaichan Yuwanasiri[2]
[1] Department of Civil Technology Education, Rajamangala University of Technology of Technology Khon Kaen Campus, Thailand; [2] Department of Civil Engineering, Faculty of Engineering, Northeastern University, Thailand

ABSTRACT

The reduction of Nitrogen Sulfide and BOD in the wastewater from buildings using aquatic plants was a study to find the ability to reduce nitrite and nitrate in the form of Total Kjeldahl Nitrogen (TKN) Sulfide and Biochemical Oxygen Demand (BOD) in the wastewater from office buildings and dormitories using 3 types of aquatic plants that were beautiful in terms of bringing it to arrange landscape in public areas, and it could be easily grown in the test pond, including 20 reeds per square meter, 10 cattails per square meter, and 10 cannas per square meter. Tested by filtering the wastewater through the sand filter layer before entering into the test pond, and retaining the water in the test pond for 1, 7 and 15 days. The results showed that the canna had the highest efficiency in BOD treatment during the 1 day storage period of 89.04% and the cattail had the highest efficiency in BOD treatment at 7 and 15 days of 92.53 % and 95.71 %, respectively. The efficiency in the treatment of TKN values during storage period at 1 day was 67 %, 7 days at 75 %, and 15 days at 82.33 %. But the cattail and canna after entering the treatment system, they had TKN values increased, it caused by not controlling the quality of the planting soil. The efficacy of sulfite treatment showed that the reed was the most effective in the treatment of sulfite during the storage period of 1, 7 and 15 days, that was 100 %. The Canna was during the storage period of 1, 7 and 15 days, it had efficiency in the treatment of sulfite at 100 % , 39.99 % and 65.21 % respectively, as well as the Cattail had efficiency in the treatment of sulfite at 100 % , 55.75 % and 91.30 % respectively.

INTRODUCTION

The water is an important resource in the lives of humans, plants and animals, it is the resource that indicates the abundance of living things on the world endlessly. For this reason, when the water is used for consumption, it causes the wastewater which is mixed into natural water sources. At present, it can see that the economic and social development, the expansion of agriculture and industry when they were compared to the beginning of the century. The water consumption has increased 5 times in the agricultural sector, and 26 times in the industrial sector [1]. In terms of population, it is estimated that in 2047 [2], the world population will increase to 9.2 billion people resulting the higher use of water for consumption, therefore the effluent is more. Especially, the effluent is from community buildings, houses with increasing population. If it was not treated before releasing to natural water sources, it will cause a balance loss. Until it will lead to problems that require enormous budgets to fix, such as the water in the water source causes the foul rot because on the water surface, it can grow well, and it covered over the surface of the water causing oxygen content in the water to be low. It makes various living things In the water cannot live, and the people can no longer use the water from that source for consumption any more.

The effluent is released from the building, which is the center of the population that uses the water throughout the day. The standards for controlling the drainage of effluent from some size and types of the buildings according to the announcement of the Ministry of Science, Technology and the Environment are used to measure the control indicators such as pH, BOD, Suspended Solids, Settleable Solids, Total Dissolved Solid, Sulfide, Total Kjeldahl Nitrogen (TKN), Fat, Oil and Grease. From the test of [3], they studied the quality of effluent from school buildings of the Faculty of Health Sciences which has many building users, it was found that it had higher BOD and TKN values than other faculty buildings. These indicators are water qualities that indicate the amount of organic and inorganic substances that are mixed with human daily life when there is more water consumption, there will be more waste affecting water quality as well. The disadvantage that comes from the quality of the effluent from the building when there is more, it can affect the environment such as the growth of abnormal water plants,

unpleasant smell, the water sources lack of oxygen, including the changing scenery. The treatment of wastewater from communities or buildings is therefore very necessary in order to maintain the quality of water sources to be balanced in accordance with the standards. At present, the wastewater treatment system used in single buildings or homes is the Onsite Treatment. The most commonly used wastewater treatment systems include septic tank, cesspool, and anaerobic pond systems, which are effective in the removal of organic matter but it cannot eliminate nitrogen and phosphorus. [4]

Wastewater treatment systems from other types of houses that are currently studied and widely used throughout the world are Wetland system using water plants to effectively eliminate contaminants in the waste, and provide beautiful scenery. It can be designed to be a recreation place in the form of small park and low cost. There is also a relatively low cost in the construction of the system, the system operation and maintenance. Therefore, the investment in the construction of the wetland system is therefore economical, suitable for economic conditions. The use of artificial ponds is therefore a suitable way to treat the wastewater from homes or communities, which reduces the discharge of wastewater into natural water sources, it also brings the wastewater back to use again, and to promote environmental conservation and biodiversity as well. [5]

Therefore, in this research, three types of aquatic plants that can be easily found in Thailand, which have already been studied, are effective in treating the wastewater, including 20 reed trees per square meter, 10 cattail trees per square meter, and 10 canna trees per square meter. The reed can treat the wastewater from the slaughterhouse until it receives the standard of industrial wastewater, both in the form of COD, TNN and it can reduce the COD, BOD and SS of the wastewater by 40-50 % [7] The cattail trees has potential to reduce the pH of the water, and it can also change the color of wastewater to fade, and reduces the toxicity in the wastewater such as it can be absorbed 56.36 % Cr and 68.47 % Cu. In addition, it was found that it can eliminate nitrogen from wastewater. [8], [9] and 20 canna trees per square meter can eliminate BOD, SS and TKN values up to 90.7 %, 98.5 %, 99.00 %, respectively. The test was conducted by filtering the wastewater through sand filter layer before entering the test pond, and the water was retained in the test pond for 1, 7 and 15 days to determine the ability to reduce nitrite, and nitrate content in the form of Total Kjeldahl Nitrogen (TKN) Sulfide and Biochemical Oxygen Demand (BOD) in the effluent from office buildings and dormitories.

MATERIALS AND METHODS

This study used 3 types of aquatic plants, Reed, Cattail, and Canna (Fig1). For use in reducing nitrite and nitrate content in the form of Total Kjeldahl Nitrogen (TKN) Sulfide and Biochemical Oxygen Demand (BOD) in the wastewater from office buildings and dormitories together with the permeability of effluent through sand filter layer using a pond of 1 .0 m diameter. Then, the effluent was released to store in the pond that planted 3 types of plants for 1, 7 and 15 days, as shown in Figure 2. In the test pond, it contained 20 reed trees per square meter, 1 0 cattail trees per square meter, and 1 0 canna trees per square meter. The test was conducted by releasing the effluent by allowing the effluent to permeate through sand filter layer before being released into the pond growing plants when the time is specified, it collected the samples at the point of discharge as shown in Figure 3.

Fig. 1 The picture of 3 types of aquatic plants., Reed, Cattail, and Canna.

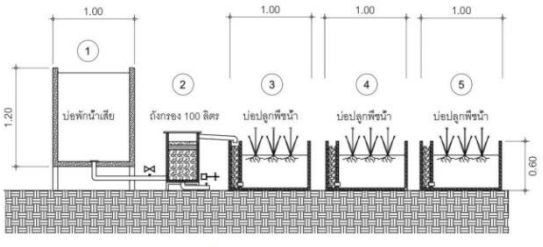

Fig. 2 The picture of wastewater treatment system from buildings using 3 types of aquatic plants.

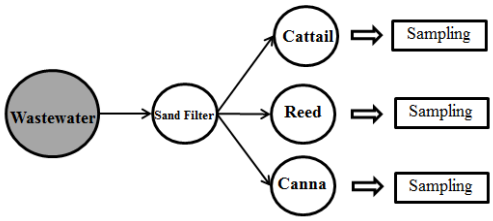

Fig. 3 The picture of the point for collecting the samples of wastewater treatment system from buildings using 3 types of aquatic plants.

From Figure 3, the nitrite and nitrate reduction test in the form of Total Kjeldahl Nitrogen (TKN) Sulfide and Biochemical Oxygen Demand (BOD) in the effluent from office buildings and dormitories using 3 types of plants. When placing the piping system and the pond according to the diagram, then growing the experimental plants in the experimental pond prepared. The plants were left to be strong for a period of 1 month, then released the effluent to store in the pond growing each type of plant for 1, 7 and 15 days, respectively. The water was collected before entering the system and after quarantine according to the specified period to test the quality of effluent according to standard testing methods from the laboratory.

RESULTS AND DISCUSSION

The analysis of the sample quality of the effluent from the building was tested with 3 types of aquatic plants to compare the efficiency of wastewater treatment by using 3 types of plants. All 3 ponds used the same effluent quality, and the effluent samples in and out of the treatment pond system was collected for quality analysis every 1 day, 7 days and 15 days from the sampling point. The effluent samples were analyzed the parameters such as nitrile and nitrate in the form of Total Kjeldahl Nitrogen (TKN) Sulfide and Biochemical Oxygen Demand (BOD). The results of the experiment were as follows:

The efficiency in BOD treatment when stored at 1, 7 and 15 days

The effluent that was fed into the treatment system growing 3 types of plants at 1, 7 and 15 days, it was found that there were BOD 73, 67 and 70 mg liters, and when passed into the treatment system, it was found that BOD removal efficiency as shown in Figure 4.

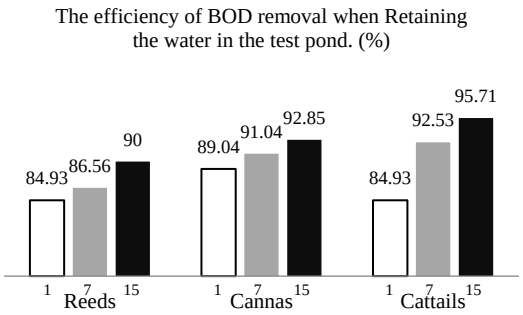

Fig. 4 The relationship between BOD value and treatment efficiency of each type of plant at 1, 7 and 15 days

From Figure 4, it was found that Canna trees had the highest efficiency in BOD treatment at 1 day of 89.04%, and the Cattail trees at 7 and 15 days it was found that it had the highest efficiency in BOD treatment for 92.53 % and 95.71 % respectively. Therefore, when considering the graphs, it showed that the BOD value tended to decrease according to the duration of storage, and when using the treatment system using 3 types of aquatic plants, BOD values were in the standard criteria of effluent from buildings. (Not more than 20 mg / l)

The efficiency in the treatment of TKN values in effluent treatment from buildings when stored at 1, 7 and 15 days

The effluent that was fed into the treatment system growing 3 types of plants when stored at 1, 7 and 15 days, it was found that there were TKN Value at 59.7, 61.2 and 60 mg liters, respectively. When it passed into the treatment pond system, it can be effective in the treatment of TKN as shown in Figure5.

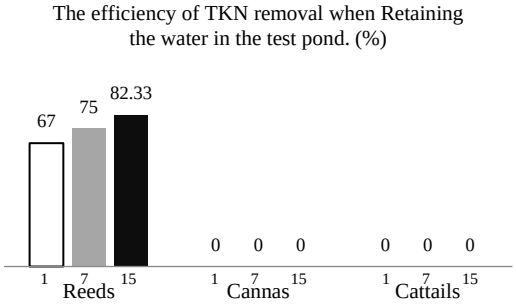

Fig. 5 The relationship between TKN values and treatment efficacy of all 3 types of plants at 1, 7 and 15 days.

From Figure 5, it was found that the reed was

effective in the treatment of TKN during the 1 day storage period was 67 % , 7 days was 75 %, 15 days was 82.33 %. But canna trees and cattail trees after entering to the treatment system, TKN values were increased due to the lack of quality control of the cultivated soil. Therefore, when considered the graph, it showed that the reed tended to decrease TKN values according to the increased retention time, and the TKN value was in the standard criteria of effluent from the building (not more than 35 mg / l)

Efficiency in the treatment of TKN values in the effluent treatment of sulfide values in the treatment of wastewater from buildings when stored at 1, 7 and 15 days

The effluent that was fed into the treatment system growing 3 types of plants at 1, 7 and 15 days, it was found that there were Sulfide Value at 1.44, 1.65 and 2.30 mg liters, respectively. When it passed into the treatment pond system of 3 types of plants, it can be effective in the treatment of sulfide as shown in Figure 6.

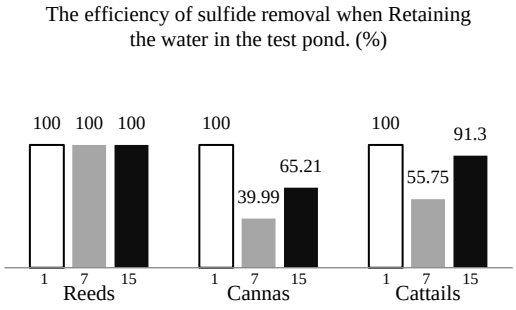

Fig. 6 Relationship between sulfide value and treatment efficiency of all 3 types of plants in storage period at 1, 7 and 15 days

From Figure 6, it was found that the reed tree had the highest efficiency in the treatment of sulfite at 1, 7 and 15 days, that was 100 %. The canna tree at 1, 7 and 15 days, it had efficiency in the treatment of sulfite of 100 %, 39.99 % and 65.21%, respectively, and the cattail tree had efficiency in the treatment of sulfite of 100 %, 55.75 % and 91.30 %, respectively. Therefore, when considered the graph, it showed that the reed is the most effective in the treatment of sulfite, and it was found that there was a tendency to decrease the sulfide value according to the storage time and the sulfide value was in the standard criteria of the effluent from the building (Not more than 1.0 mg / l)

CONCLUSIONS

The experiment results found that the cattail tree could reduce the BOD value most effectively at 15 days. It could reduce the BOD value 95.71 %, which the BOD concentration from 70 to 3 and it was found that the reed could reduce TKN value to be the most effective at 15 days, and it could reduce TKN value of 82.33 %, which the TKN concentration from 60 to 10.6 . In addition, it was found that the reed could reduce the sulfite value most effectively at 1, 7 and 15 days, it could reduce the sulfite value of 100 %. It showed that all types of plants could increase the effluent quality to be in the standard criteria of effluent quality from the building.

ABSTRACT

In this research, the efficiency of solar powered water pumping systems for drip irrigation is studied through solar powered water pumping systems and drip irrigation by doing the actual tests on the agricultural land by dividing into 3 tests, 1. the relationship between the discharge and water level, 2. the relationship between the light intensity measured from the solar meter and the discharge of the water and 3. the efficiency of solar powered water pumping machine in the form of efficiency of emission uniformly drip irrigation (EU). The tests were conducted on an agricultural field with the area of 1600 m^2. From the tests, it was observed that the solar powered water pumping machine reached the maximum efficiency in the period of 11:00h to 13:00h. The maximum value of light intensity was 1038.9 W/m^2. The discharge of the water varies as functions of water level in the tank and efficiency of emission uniformly drip irrigation. There were 28 lines of drip irrigations spread on the hold area of the testing field. When all of the drippers were opened, it was observed that the efficiency of emission uniformly drip irrigation from the lowest until the highest water level was 71% to 84% which was in the condition of an acceptable design, and when switching by opening only 14 lines (one line was closed, its neighbor was opened) of drip irrigation, it was found that the efficiency of emission uniformly from the lowest to the highest water level was 81% to 86% which was in the condition of a good design.

Keywords: Water Resources Management, Irrigation, Solar Powered, Pumping System and Drip Irrigation

INTRODUCTION

Water plays a very important role in plant productions since it is an important factor for plant growth and improving the productivity in both quantity and quality which is the farmers' main goal. In some areas, water resources for agricultures are insufficient for cultivation; especially, in the year of drought or irregular rainfall, typically in the north-east part of Thailand which is a hot and dry weather region, resulting the plants demand high amount of water. Therefore, the requirement of drip irrigation in this region is high. However, the type of soil in most areas here is sandy soil with low water holding capacity. When the amount of drip water irrigation is greater than the water holding capacity of soil, the state of water repellency in soil occurs, and the plant nutrients stay beyond the area or length of the plant roots. In this case, the water drip irrigation should be provided in low amount, but frequently. This method could cost some budgets on labors and water losing from leaks while transporting water along the pipes in the water drip irrigation systems [1]. To avoid these problems, farmers should consider carefully about the water sources, methods of water transportation, water storages, and appropriate procedures of making drip irrigation systems to make plants grow well in all seasons by trying to use water at the maximum level of effectiveness because in the north-east part of the Kingdom is the irregular rainfall area and may lead to have water crisis in some seasons. Water resource management for the north-east part of Thailand is now a very important issue for farmers in order to be able to use the existing limited amount of water reach the maximum results.

By receiving the helps from Drought Relief Volunteer Center, The Regional Irrigation Office 6, Khon Kaen Province, a solar powered water pumping system has been implemented. This pumping machine generates by using the power from the sunlight instead of diesel fuel, gas, and coal. This solar powered water pumping system is not only cheaper than diesel, gas, and coal, but it can also reduce noise and pollutions in the environment

as well. In short, using the solar powered water pumping system provides lower cost than using diesel fuel from 2 to 4 times. Moreover, it can keep the atmosphere clean, low cost in maintenance, no need to spend money on any type of fuel [2]. By applying this method together with water resource managements using drip irrigation systems, water can be transported from the sources and stored in a certain place to be used in cultivation or other agricultural purposes in the drought season. This solution can be counted as an efficient method in using water and suitable for the north-east area of Thailand since the drip irrigation system is a system that provides water at the base of the plants little by little which is more economical than other types of irrigations. However, in the real process, it has not had any research on the efficiency of this system yet.

Therefore, it is necessary to do the research and collect the data to find the efficiency of solar powered water pumping systems for drip irrigation. The tests were done on a farmer's agricultural land located in Khum Kao Sub district, Khao Wong District, Kalasin Province to get information and data to be used and applied so that it can produce good benefits for farmers in the future.

MATERIALS AND METHODS

To reach the goals of the study, the data and analyses of the efficiency of solar powered water pumping systems for drip irrigation must be collected. The methodologies are as below:

1.1 Install the solar powered water pumping system which consisted of a 1-inch pump controller, 2 panels of solar cell with the capacity of 150 W, 1 set of motor brushless of 350 W, a motor controller box, an airware, water tanks, pipes, pipe fittings, an agricultural water filter, and a valve as shown in Fig 1.

1.2 Collect the data of the light intensity every 1 hour from 6.00h until 18.00h by using solar power meter measuring 5 times per day. Then calculate the average value of 7 days to find the efficiency of solar cells at the different light intensities.

1.3 The test of the relationship between the discharge and water level in the tank can be done by measuring the discharge of water in the tank and divide the water level into 200 liters per portion to calculate the discharge as a function of height (water level).

Fig 1. The solar powered water pumping systems

1.4 The calculation of the efficiency of the emission uniformly full and half drip irrigation systems can be done by collecting the average discharge of all drippers on the field, and the value of emission uniformly (EU) can be calculated from equation 1.

$$Eu = qn/qa \times 100\% \quad (1)$$

where

Eu = Emission uniformly of water measured on the testing field

qn = average discharge of the minimum values (1/4) of the data measured from the testing field

qa = average discharge of all drippers on the testing field

The value of Eu for drip irrigation system is sometimes considered as an efficiency of drip irrigation on the testing field (Ea). For the drippers which are used with plants planted very close to each other, Eu is considered as follow [3]:

Eu>80% considered as a good drip irrigation system

70<EU<80% considered as an acceptable drip irrigation system

70>Eu considered as a weak drip irrigation system, and the system should be redesigned

RESULTS AND DISCUSSION

1. Results of the test on the relationship between light intensity and discharge

After the analysis, a result is obtained in the function of solar power and time period as shown in Fig 2.

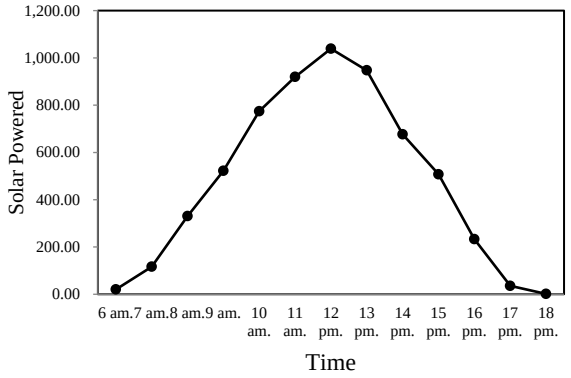

Fig 2 The relationship between solar powered and time

Fig 2 shows that the relationship between the average light intensity and time period happens in the form of parabolic curve. The light intensity increases while the time period also increases until it reaches the maximum value at 12:00h (vertex of the curve) . Then the light intensity decreases slowly until zero at 18:00h.

Therefore, choosing the average intensity of solar power which is suitable to the needs of different plants can be done from the amount of water requirement subjected to the relationship between time period and light intensity which lead to make the comparison between the discharge and the solar power as shown in Fig 3.

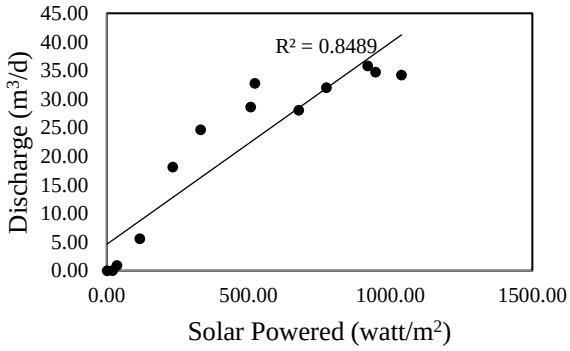

Fig 3 The efficiency of solar powered water pumping systems

Fig 3 proves that the test results of the data collection of light intensity is compared to the discharge of the pumping machine. Based on the analysis, the results of the test of the light intensity data collection compared to the discharge of the pumping machine varies as functions of time and light intensity. The maximum discharge of the pumping machine is 2.55 L/s at 11:00h. The study [4] of developed solar powered pumping machine showed that it can pump at the maximum discharge of 3.15 liters per second, where, the discharge varies as a function of time, and the period for pumping is limited only 4 hours per day. However, if the solar cells are charged while pumping, the pumping machine can work longer in the constant amount of discharge of 1.5 liters per second.

2. Results of the test on the relationship between the discharge and water level in the tank

The test of the relationship between the discharge Q and the water level in the tank can be done by measuring the discharge of water in the tank and divide the water level into 200 liters per portion to calculate the discharge Q compared to the water level h as shown in Fig 4.

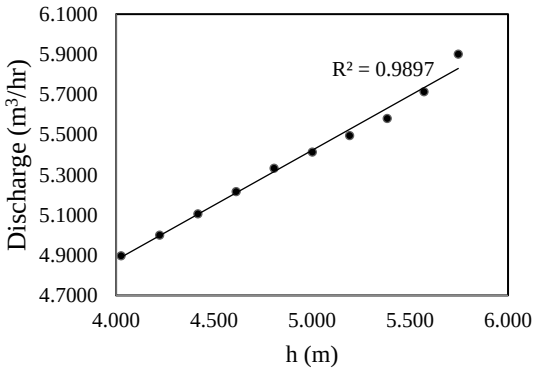

Fig 4 Relationship between the discharge and water level in the tank

Fig 4 shows about the relationship between the discharge and water level in the tank. After releasing water from the state of full tank at the level of 5.746 until the tank runs out of water at the level of 4.025, it has been observed that the discharge varies as a function of water level in the tank. The maximum discharge at full water tank and the minimum discharge when the tank runs out of water are 5.9016 m^3/hr and 4.898m^3/hr , respectively.

3. The efficiency of emission uniformly (EU) drip irrigation

The calculation of the efficiency of emission uniformly can be done by collecting the average discharge data of all drippers on the testing field. In this step, the test is divided into 2 types. Type 1: Find the value of EU by opening all of the drippers in the field (28 lines of drippers). Type 2: Find the value of EU by opening only 14 lines of drippers in the field (switching). Then note the results from 3 points per line. The results from the test are as the following:

3.1 Value of EU when all drippers are opened

From the test, when all the drippers (28 lines) are opened and note the results from 3 points per line, it provides a result as shown in Fig 5.

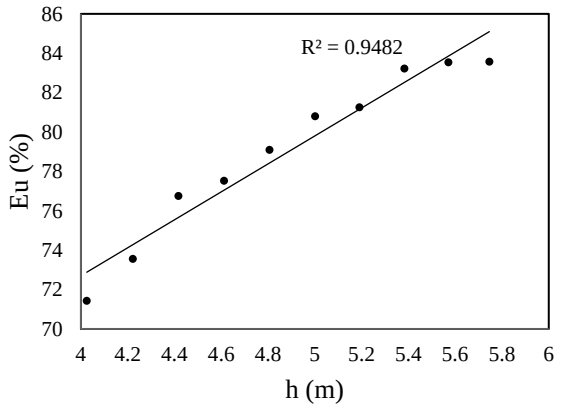

Fig 5 Efficiency of emission uniformly drip irrigation when all drippers are opened

By measuring the results from all 28 lines of the hanging drippers, it is shown that the value of emission uniformly (EU) at the lowest to highest water level lies from 71%s to 84%, which is considered to be an acceptable design.

3.2 Value of EU when 14 lines of drippers are opened

The drippers on the hold testing field are opened only 14 lines by switching one by one (one line is opened, its neighbor is closed). The results are measured from 3 points per line. After finishing the test, it provides the value of EU as shown in Fig 6.

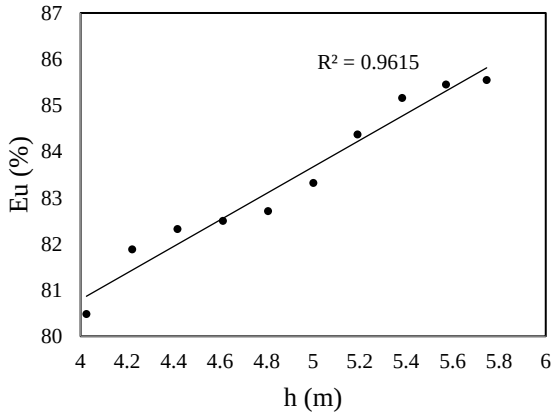

Fig 6 Efficiency of emission uniformly drip irrigation opened only 14 lines of drip irrigation

By measuring the results from 14 lines of the hanging drippers, it is shown that the value of emission uniformly (EU) at the lowest to highest water level lies from 81% to 86%, which is considered to be a good design of drip irrigation.

CONCLUSIONS

The study of the efficiency of solar powered water pumping systems for drip irrigation is done by pumping the water using solar powered water pumping machine from the canal to store in the tank with the volume of 2000 liters. The tank is installed at 2 meters above ground surface, and the water is transported to the drip irrigation. Based on this study, it has been concluded that the solar powered pumping machine under the petty patent of Drought Relief Volunteer Center, The Regional Irrigation Office 6, Knon Kaen, Thailand provides a good efficiency and can be pumped in the discharge of 0.43 L/s during 7:00h. This period is a low solar power absorbing period. The solar power increases all the way up to 11:00h which is the period that provides high intensity of light and can be pump up to 2.5 L/s. When this solar powered water pumping machine is brought to work with the drip irrigation system by installing the tank at high level above ground surface, it has been found that in the area of the testing field, 1600m^2, filled with the drip irrigation systems for 28 line provided the efficiency of emission uniformly (EU) from 70% to 80% which lies in the condition of acceptable design. In case of opening the drippers only 14 lines (switching) which conform to the farmers' real work, it provides the efficiency of emission uniformly greater than 80%, and this is considered as a good design.

PREPARATION OF DESALINATION AGENT FROM CA-TYPE CLAY MINERALS

Fumika Sekihata[1], Takaaki Wajima[2]
[1,2]Graduate School to Science and Engineering, Chiba, Japan

ABSTRACT

The desalination technology of seawater is considered to secure water and food in recent years, and a new simple desalting material to decrease the high concentration of sodium chloride in seawater is desired. In this study, preparation of the desalting agent from two Ca-type clay minerals, natural zeolite and Ca-Fe type layered double hydroxide (LDH), attempted to desalinate seawater for agricultural water.

Natural zeolites used in this study were mordenite-type zeolite from Fukushima prefecture, Japan and clinoptilolite-type zeolite from Kagoshima prefecture, Japan, and raw and Ca-substituted zeolites were used for seawater desalination. Regardless of zeolite type, desalination behaviors of Ca-substituted zeolite were almost same as those of raw zeolite. The salinity and pH of seawater were 3.46% and 8.0, respectively, while clinoptilolite decreased the salinity to 3.20%, mordenite decreased to 2.09%, above 5.0 g/L zeolite addition. As increasing the Calcined Ca-Fe LDH addition to seawater, the salinity decreased to 3.3%, and pH of the solution increased to pH 11.5, and then became almost constant above 2.0 g/L addition of Calcined Ca-Fe LDH. As increasing the mixing ratio of Calcined Ca-Fe LDH to raw mordenite, the salinity decreased to 0.8% (79.2% reduction) while pH of the solution was neutral (about 7.6~8.0). Radish sprouts could be harvested using the seawater treated with a mixture of raw mordenite-type natural zeolite and Calcined Ca-Fe LDH, although those could not be harvested using seawater, the seawater treated with natural zeolite or Calcined Ca-Fe LDH.

Keywords: Natural Zeolite, Calcined Ca-Fe LDH, Desalination, Agricultural Water

INTRODUCTION

The total amount of water resources on the earth is about 1.3 billion km^3, but seawater is about 97.5% and freshwater is only about 2.5%, and the freshwater available to mankind is only about 0.01% of total water resources. About 70% of freshwater is used for the agricultural uses. In recent years, water demand has increased due to the increase in the world population, and the development of technology to obtain agricultural water from high salinity water, such as seawater, is considered in order to secure food. Multi-stage flash evaporation and reverse osmosis membrane are typical seawater desalination techniques and are often used for the securing of drinking and industrial water, which required high purity. Therefore, it is a high cost for the production of agricultural water and a simple new desalination method is desired.

In this study, we try to develop a new desalting material that reduces the high concentrations of sodium chloride in seawater causing salt damage to the level at which crops can grow [1]. In previous studies, we can prepare the cultivation solution, which can be used for radish sprout growth, from seawater by two-stage treatment of seawater with calcined hydrotalcite and mordenite natural zeolite [1]. Additionally, radish sprouts can be grown in the solution prepared from seawater treated by Ca-A synthetic zeolite [2], and in calcined-layered double hydoroxide (LDH), Ca-Fe LDH calcined at 500°C has high desalting ability [3].

In this study, a simple desalting material with high desalting ability was prepared using two Ca-type clay minerals, Ca type natural zeolite and calcined Ca-Fe LDH. We evaluated the desalting capacity of the new desalting material for two Ca-type clay minerals.

EXPERIMENTAL

Two types natural zeolites, clinoptilolite type natural zeolite obtained from Koriyama, Kagoshima prefecture, Japan, and mordenite type natural zeolite obtained from Iizaka, Fukushima prefecture, Japan, were used as natural zeolite sample in this study.

The following operations were performed to prepare Ca type natural zeolite. 5 g of natural zeolite was added to 100 mL of 5 mol/L $CaCl_2$ solution. Stirring (1000 rpm) was carried out at 80 ° C for 1 hour and then filtered. The filtered solid was added into the fresh $CaCl_2$ solution and stirring was carried out again. This process was repeated 2 times. After that, the soiled was washed with 1 L of distilled water, dried in a drying oven to obtain Ca-type natural zeolite sample.

Calcined Ca-Fe LDH was prepared as follows. A

mixed solution of Ca^{2+} and Fe^{3+} (Ca/Fe = 2) was prepared from 0.2 M $CaCl_2$ solution and 0.1 M $FeCl_3$ solution, and dropped into a 0.3 M NaCl solution at 4 mL/min. Stirring was performed for 6 hours with bubbling nitrogen gas, and the pH of the NaCl solution was maintained at 12.5 by dropwise addition of NaOH during stirring. After stirring, the product was filtered and dried, and the resulting product was calcined at 500°C for 1 hour in electric furnace to obtain calcined Ca-Fe LDH.

Desalination Ability

Seawater was collected from the surface layer of Imari bay, Saga prefecture, Japan and filtered. Chemical composition, salinity and pH of seawater are shown in Table 1.

Table 1 Chemical composition, salinity and pH of seawater (mg/L)

	Sea Water
SO_4^{2-}	3137
Cl^-	26137
Na^+	9686
K^+	478
Mg^{2+}	1527
Ca^{2+}	471
Fe^{3+}	0.02
Salinity(%)	3.46
pH	8.0

The desalting ability was evaluated as follows. Raw and Ca-type natural zeolite, calcined Ca-Fe LDH, and the mixtures of natural zeolite and calcined Ca-Fe LDH with various mixing rations was added to 20 mL of seawater, and shaken for a predetermined time. After shaking, the solution is filtered, and the pH of the filtrate is measured by pH meter (Horiba, F-72), salinity is measured by salinity meter (Mothertool, YK-31SA), the concentrations of Na^+ K^+, Mg^{2+}, Ca^{2+}, Cl^-, and SO_4^{2-} in the filtrate, were measured with an ion chromatograph (Tosho, IC-2010) and Fe^{3+} content in the filtrate was determined using an atomic absorption spectrophotometer (Perkin Elmer, AAnalyst 200). The reduction rate of each ion after treatment was calculated using equation (1).

$$R=(C_0-C)/C_0\times 100 \quad (1)$$

where R is reduction rate (%), C_0 is each ion concentration (mg/L) in initial solution, and C is each ion concentration (mg/L) in the solution after desalination of the seawater.

Furthermore, the residue was dried, and the structure was confirmed by a powder X-ray diffraction apparatus (Rigaku, MiniFlex 600).

Growth Test

Radish sprouts (30 seeds) were used for 10 days growth Test. Seawater solution, seawater treated with mordenite type natural zeolite (10 g/ 20 mL), the seawater treated with Calcined Ca-Fe LDH (0.6 g/ 20mL) and the seawater treated with a mixture of mordenite type natural zeolite (10 g/ 20mL) and Calcined Ca-Fe LDH (8 g/ 20mL) was given by a spray every day, and germinations of radish sprouts were observed.

RESULT AND DISCUSSION

Seawater Desalination of Zeolites

Fig. 1 shows the salinity and pH of seawater after treatment with natural zeolite. The white plots indicate clinoptilolite use and the black plots indicate mordenite use. For the raw and Ca-type clinoptilolite natural zeolite, when the addition amount increased to 1.0 g/ 20 mL, the salinity decreased to about 3.20% (about 5% reduction), and became constant above 1.0 g/ 20 mL. For the raw and Ca type mordenite natural zeolite, the salinity decreased to about 2.09% (about 38% reduction) when the addition amount increased to 10 g/ 20 mL. It was noted that the pH of the solution after desalination was 7.4 to 8.0 for all samples.

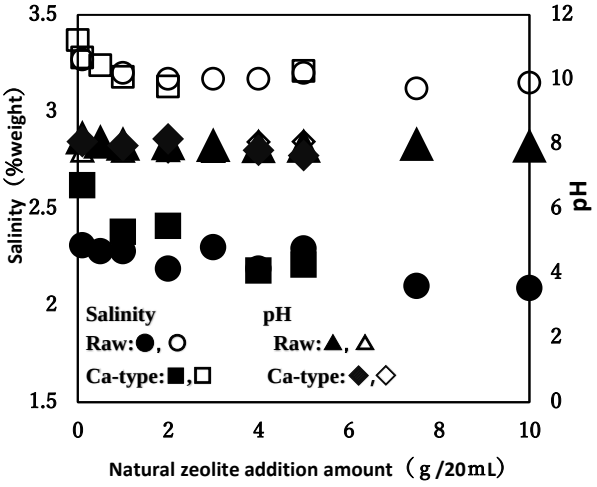

Fig. 1 Salinity and pH of seawater after treatment of natural zeolite

Fig. 2 shows the reduction of each ion in seawater after treatment with clinoptilolite zeolite. Fig. 3 shows the reduction of each ion in seawater after treatment with clinoptilolite zeolite and mordenite zeolite, respectively.

In clinoptilolite zeolite, the contents of Na^+, Mg^{2+}, Cl^- and SO_4^{2-} in the solution treated with raw and Ca

type natural zeolite are reduced (about 15~30%) when the addition amount is more than 1.0 g/ 20 mL. K^+ reduction is about 60~75% at more than 0.5 g/ 20 mL. In mordenite zeolite, the reduction of Na^+ and K^+ in the solution after zeolite treatment is about 65% when the addition amount is 10 g/ 20 mL, Mg^{2+} reduction was about 17~26% at more than 0.5 g/ 20 mL addition, and Cl^- and SO_4^{2-} reduction are about 31~51% at more than 0.1 g/ 20 mL.

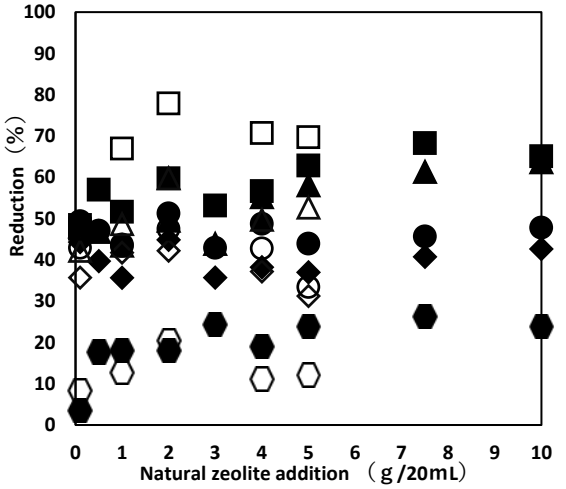

Fig. 2 Reduction of each ion in seawater after treatment of clinoptilolite natural zeolite
Raw: ◆:SO_4^{2-} ●:Cl^- ▲:Na^+ ■:K^+ ⬣:Mg^{2+}
Ca-type: ◇:SO_4^{2-} ○:Cl^- △:Na^+ □:K^+ ⬡:Mg^{2+}

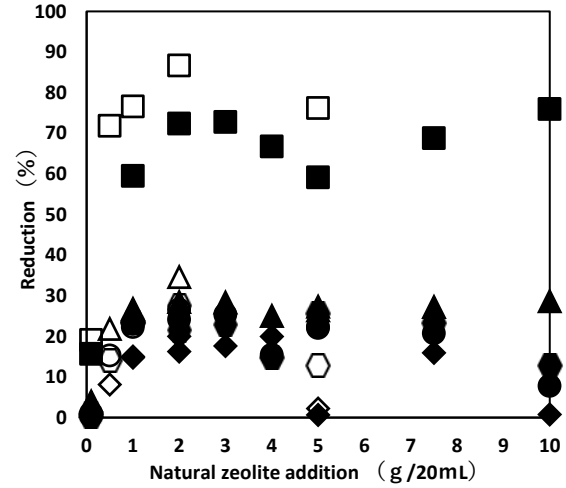

Fig. 3 Reduction of each ion in seawater after treatment of mordenite natural zeolite
Raw: ◆:SO_4^{2-} ●:Cl^- ▲:Na^+ ■:K^+ ⬣:Mg^{2+}
Ca-type: ◇:SO_4^{2-} ○:Cl^- △:Na^+ □:K^+ ⬡:Mg^{2+}

From these results, it was found that the desalting ability of Ca-type substituted natural zeolites is the same as that of raw zeolites, and mordenite type natural zeolite has higher desalting ability than clinoptilolite type natural zeolite. The decrease of Na^+, Mg^{2+}, Cl^- and SO_4^{2-} in seawater after treatment of mordenite-type natural zeolite is more than that of clinoptilolite type natural zeolite.

Fig. 4 shows the XRD patterns of clinoptilolite before and after desalination treatment. Fig. 5 shows the XRD patterns of mordenite before and after desalination treatment. It was confirmed that the peak intensity and pattern after treatment were the same for both raw and Ca-type natural zeolites.

Seawater of Desalination Calcined Ca-Fe LDH

Fig. 6 shows the salinity and pH of seawater after treatment with calcined Ca-Fe LDH. The salinity was reduced until 0.6 g/ 20 mL of calcined Ca-Fe LDH addition, and the salinity of seawater was reduced from about 3.55% to about 3.30% (about 6.5% reduction). The pH after desalination increased to about 11.0 ~ 11.5 when more than 0.4 g/ 20 mL of calcined Ca-Fe LDH was added because OH^- is released when calcined Ca-Fe LDH intercalates anions into layers by reconstruction of LDH structure [3].

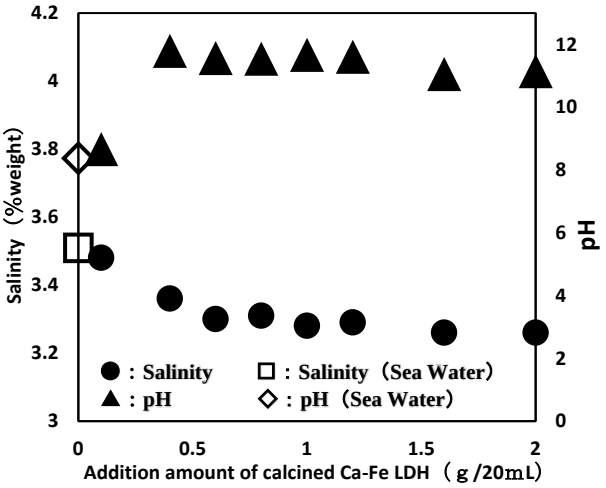

Fig. 6 Salinity and pH of seawater after desalination of calcined Ca-Fe LDH

Fig. 7 shows reduction of each ion concentration in seawater after treatment. The reduction of SO_4^{2-}, Cl^-, Na^+ and K^+ increased to 20 ~ 30% up to 0.6 g/ 20 mL of calcined Ca-Fe LDH. The reduction of Mg^{2+} was about 70 ~ 80% regardless of additional amount of calcined Ca-Fe LDH. It is considered that these decrease causes the decrease of salinity. It is noted that after the desalination of seawater, the concentration of Ca^{2+} and Fe^{3+} increased. Because the Ca^{2+} and Fe^{3+} would be released from calcined Ca-Fe LDH into the seawater.

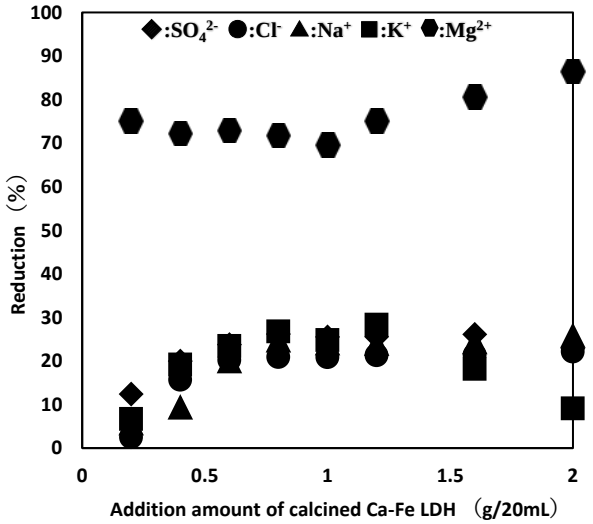

Fig. 7 Reduction of each ion concentration after seawater desalination using calcined Ca-Fe LDH

The XRD of Ca-Fe LDH, calcined Ca-Fe LDH after seawater desalination are shown in Fig. 8. The peaks of Ca-Fe LDH were confirmed before calcination. After calcination, it was confirmed that no Ca-Fe LDH peak appeared. The peaks of LDH were confirmed in all the calcined Ca-Fe LDH after desalination of seawater. It is considered that desalination was occurred by the reconstruction of calcined LDH. It is noted that the formation of calcium carbonate ($CaCO_3$) were confirmed in calcined Ca-Fe LDH after desalination.

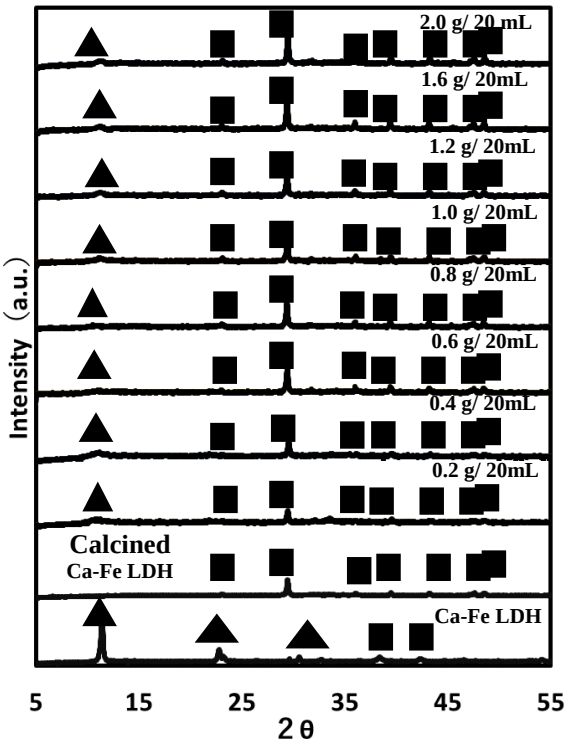

Fig. 8 XRD pattern of Ca-Fe LDH, calcined Ca-Fe LDH and the product after treatment with various Ca-Fe LDH
▲:Ca-Fe LDH ■:$CaCO_3$

Desalination of Seawater with a Mixture of Natural Zeolite and Calcined Ca-Fe LDH

In order to determine the optimum ratio for maximizing desalting ability of the mixture of natural zeolite and calcined Ca-Fe LDH, 0 to 8.0 g of calcined Ca-Fe LDH is mixed with 10 g of raw mordenite zeolite, and the desalting ability was examined. Fig. 9 shows the salinity and pH of seawater obtained by treatment of the mixture of various amount of calcined Ca-Fe LDH and 10 g of raw mordenite type natural zeolite.

The salinity decreased to 0.70% when 8.0 g of calcined Ca-Fe LDH was added to 10 g of raw mordenite zeolite (about 79.2% reduction) and the pH after treatment was about 7.6 to 8.0.

Fig. 10 shows the reduction of each ion and Fig. 11 shows each ion concentration in seawater after treatment with a mixture of calcined Ca-Fe LDH and mordenite zeolite. It was confirmed that the concentration of Na^+, K^+, Mg^{2+}, Cl^- and SO_4^{2-} decreased. When 8.0 g of calcined Ca-Fe LDH is added to 10 g of raw mordenite zeolite, NaCl which

causes salt damage is reduced, and 59% of Na^+ and 71% of Cl^- were removal by natural zeolite with cation exchange ability and calcined Ca-Fe LDH with anion removal ability, respectively. The decrease rate of each ion in seawater was SO_4^{2-}: about 87.7%, Mg^{2+}: 96.8%, and K^+: about 64.0%. Ca^{2+} and Fe^{3+} increased with increase of the amount of calcined Ca-Fe LDH. It is considered that the increase in contents of Ca^{2+} and Fe^{3+} is released into seawater from mordenite zeolite and calcined Ca-Fe LDH.

From these result, it is considered that when the mixture of two clay minerals is used, the salinity decreases to the level that can be used for agriculture because more than 80% of SO_4^{2-}, Cl^-, Na^+ and Mg^{2+} decrease.

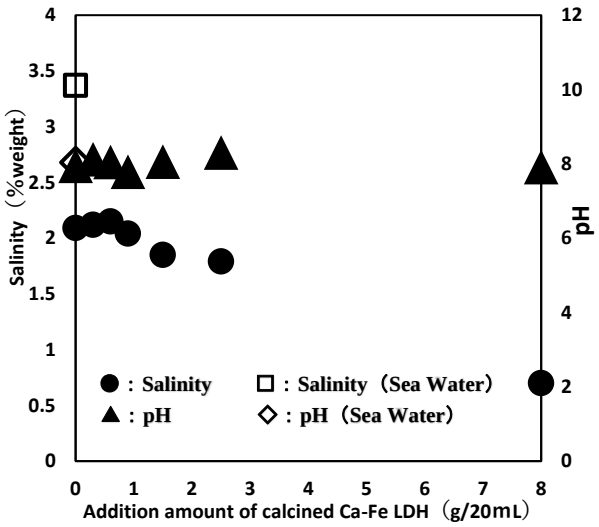

Fig. 9 Salinity and pH of seawater after treatment with mixtures of mordenite natural zeolite and calcined Ca-Fe LDH

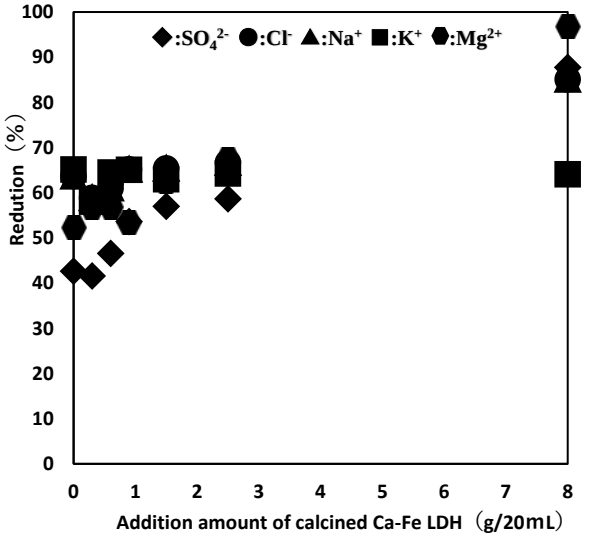

Fig. 10 Each ion reduction of seawater after treatment with a mixture of mordenite type natural zeolite and calcined Ca-Fe LDH.

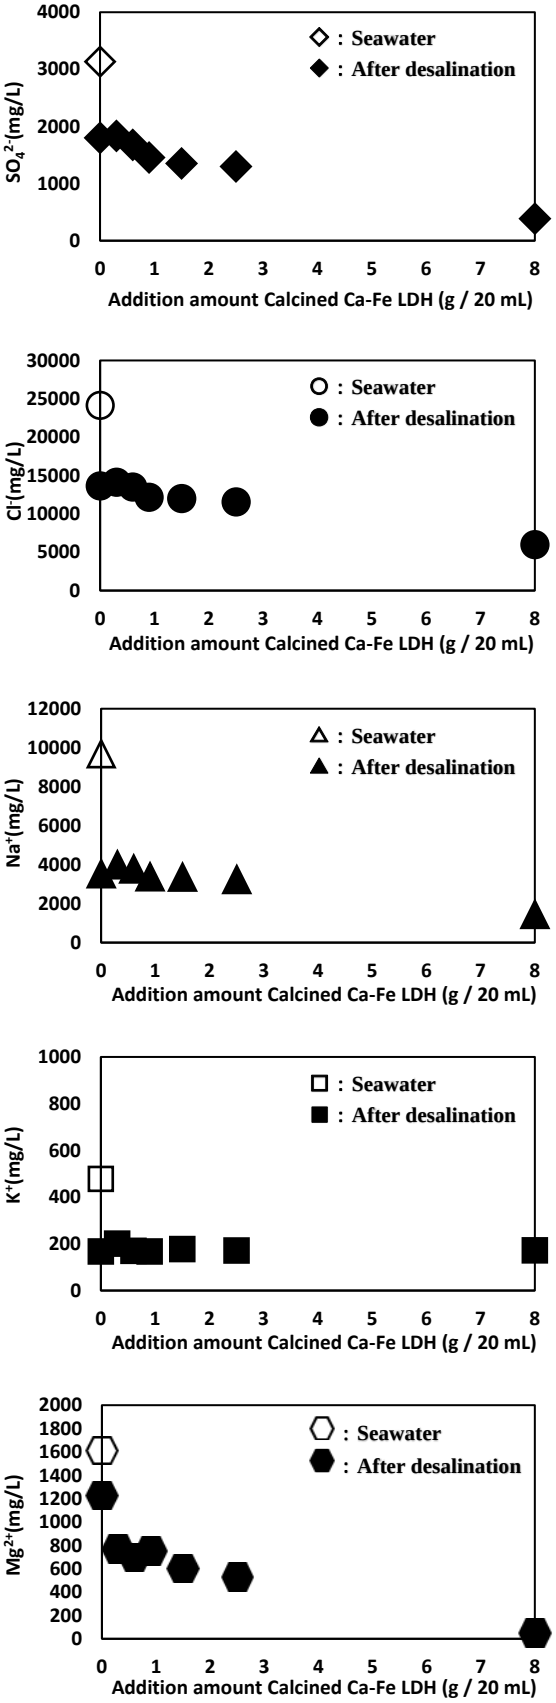

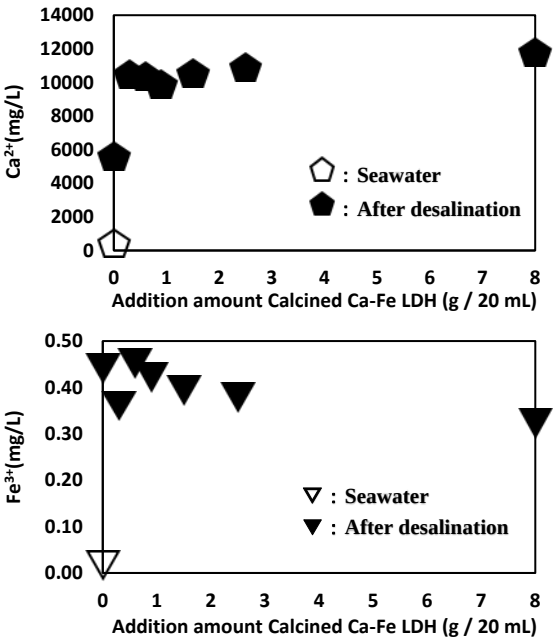

Fig. 11 Each ion concentration of seawater after treatment with the mixture 10 g of mordenite type nature zeolite and various amounts of calcined Ca-Fe LDH

Cultivation of Radish Sprouts

Table 2 shows the concentration of each ion of (a)seawater, and the seawater treated with (b) raw mordenite zeolite (10 g/20 mL), (c) calcined Ca-Fe LDH (0.6 g), and (d) the mixture of raw mordenite zeolite (10 g) and calcined Ca-Fe LDH (8.0 g). When desalting seawater with natural zeolite, calcined Ca-Fe LDH, and a mixture of natural zeolite and calcined Ca-Fe LDH, the concentrations of Na^+, K^+, Mg^{2+}, Cl^- and SO_4^{2-} decreased, and Ca^{2+} and Fe^{3+} increased.

The germination of radish sprouts was confirmed using seawater treated with a mixture of mordenite type natural zeolite and Calcined Ca-Fe LDH, while they can't germinate using seawater, the seawater treated with natural zeolite and that with Calcined Ca-Fe LDH (Fig. 12).

Table. 2 Each ion concentration of seawater and seawater after addition of desalination material (mg/L)

Sample	(a)	(b)	(c)	(d)
SO_4^{2-}	3137	1800	2391	386
Cl^-	26137	13646	20859	5997

Fe^{3+}	0.02	0.44	0.17	0.39
Salinity(%)	3.46	2.09	3.29	0.70
pH	8.0	7.83	11.6	7.80

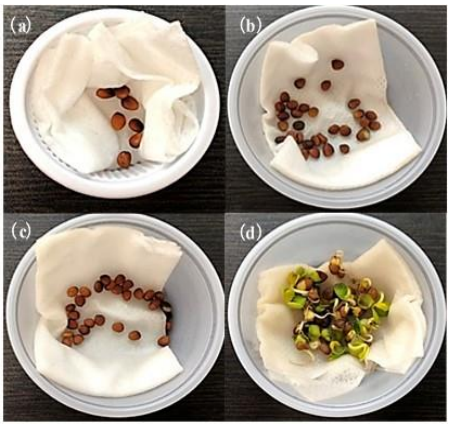

Fig. 12 Observation of radish sprouts after 10 day growth using (a) seawater, and the seawater treated with (b) raw mordenite zeolite (10 g/20 mL), (c) calcined Ca-Fe LDH (0.6 g), and (d) the mixture of raw mordenite zeolite (10 g) and Calcined Ca-Fe LDH (8.0 g)

CONCLUSION

For the development of desalination material to obtain agriculturally usable freshwater from seawater for stable supply of water resources, two Ca types clay minerals, Ca type natural zeolite and calcined Ca-Fe LDH, were used for desalting from seawater.

When adding 10 g of mordenite zeolite, the salinity decreased to about 2.09% (about 38% reduction), and mordenite indicates higher desalting ability than the clinoptilolite zeolite. Reduction of the salinity using Calcined Ca-Fe LDH was about 6.5%, and pH rises to about 11-11.5 from about 8.0.

Seawater were treated with the mixture of raw mordenite zeolite (10 g) and Calcined Ca-Fe LDH. With increasing the Calcined Ca-Fe LDH addition, the salinity decreased to 0.70% below the available salinity for agriculture (about 1.0%) and pH is neutral. When using desalting of seawater treated with a mixture of mordenite zeolite and Calcined Ca-Fe LDH, the germination of radish sprouts was confirmed.

ABSTRACT

Route tracking's stabilization control in autonomous vehicles is the system invented to response to the need of use of vehicles' transportation in various industrial factories. This system helps in controlling the autonomous vehicles to move in programmed routes and time efficiently and provides safety from work of other vehicles in the factories. The study of this work uses transportation routes regarding to one of the automobile factories to calculate the transportation paths by using Microsoft Excel program. The paths are scaled in comparison with the factory patterns and the data is used to create equations with a linear relation between the speed and time of vehicles. The acquired equations are further applied with the Fundamental Equations of Constrained Motion to find a force that controls the system so that the vehicles move in their designated routes. The analyzing processes consist of three parts: unconstrained system, constraint equations, and constrained system respectively. According to the study and simulation of vehicles' movement, it is found that the approach using the Fundamental Equations of Constrained Motion is easy especially in calculation when there are a complex system with many constraints. Furthermore, there are some flexibility in choosing parameters to control errors to be small or approaching to zero with less time. The results guarantee that satisfaction because not only vehicles move along the routes and time specified but also they can move according to all conditions that are set perfectly. That is the main reason for more efficient future production of industrial plants.

Keywords: Stability, Tracking Control, The Fundamental Equation, Constrained Motion

INTRODUCTION

In various industrial plants, loading or unloading objects may result in errors such as wrong loading places or relocation time. According to the need to control inventions, the incompetent person can make moving objects more valuable and more accurate.

Unmanned Ground Vehicles (UGVs) can be used to transport items from one point to another as needed. It is driven by a computer-controlled automation system [1] – [3]. A creation of control is a significant part that has an effect on controlling errors of UGV's maneuvers. From literatures, it is found that the adaptive control is a controller that requires multiple adapting parameters used in calculation, causing complexity. The sliding mode control [3] is a controller that takes into account an uncertainty in the environment and requires fewer calculation parameters. However, it causes chattering of a control signal that may encourage high frequency dynamics, which are usually ignored in the model. Therefore, we have chosen to use the Fundamental Equations of Constrained Motion [8] to create a controller and learn how to reduce error values in a short time. This is a reason that motivates us to develop the stability control of the UGV system to follow paths and to be more stable with least time as possible. However, in order to make movements of vehicles to be more effective, both conditions in terms of position and time are considered. Therefore, it is expected to result in more efficient driving of unmanned vehicles

In general, studying movements of any objects uses Newton's law of motion, which is the main rule in calculating movements of various objects. It is an equation that relates to an acceleration of masses which is a vector quantity, making it necessary to consider directions in studying movements of objects [4]-[5]. However, in this work, Lagrange's equation related to kinetic energy and potential energy, which are scalar quantities, is chosen, thus eliminating the need to consider the direction in studying movements of unmanned ground vehicles. When applying this movements, which are relying on moving conditional equations, a stable trajectory control of unmanned ground vehicles is achieved by analyzing the movements using the Fundamental Equations of Constrained Motion (FECM) [6]-[8]. A development of a numerical simulation is also done in order to verify stability of the movements of the unmanned ground vehicles (UGVs).

In real life, work does not consist of the sole purpose of working. But we still have to think about the correctness and safety in that work especially by working in conjunction with various vehicles. There are errors that can cause accidents, resulting in the development of unmanned vehicle control systems in order to meet the need to reduce the risk of work hazards caused by human work and the above limitations.

THE FUNDAMENTAL EQUATIONS

The uncontrolled system is described in which the coordinates are all assumed independent of each other. The equation of motion of this system is given using Lagrange's equation, by

$$M\ddot{q} = Q \tag{1}$$

with the initial conditions $q = 0$ and $\dot{q} = 0$. q is the generalized coordinate n-vector, $M > 0$ in the n by n mass matrix which is a function of q and t. Q is an n-vector, called the 'given' force. From Eq. (1) the acceleration of the uncontrolled system is given by

$$a := \ddot{q} = M^{-1}Q. \tag{2}$$

On this uncontrolled system, a set of control requirements is imposed as constraints. The uncontrolled system is now subjected to the m sufficiently smooth control requirements given by

$$\phi(q, \dot{q}, t) = 0 \tag{3}$$

where $r \leq m$ equations in the equation set Eq. (3) are functionally independent. The control constraints described by Eq. (3) include all the usual varieties of holonomic or non-holomonic constraints. The presence of the control requirements does not permit all the components of the n-vector $q = 0$ and $\dot{q} = 0$ to be independently assigned. The initial conditions are assumed to satisfy the m control requirements.

Differentiating the control requirements Eq. (3) with respect to time t, the constraint relation is obtained as

$$A(q, \dot{q}, t)\ddot{q} = b(q, \dot{q}, t) \tag{4}$$

where A is an m by n matrix whose rank is r and b is an m-vector. It is noted that each row of A arises by appropriately differentiating one of the m control requirements in the set given in Eq. (3). The equation of constrained motion of the system is given by

$$M\ddot{q} = Q(q, \dot{q}, t) + Q^C(q, \dot{q}, t) \tag{5}$$

where Q^C is the control force n-vector that arises to ensure that the control requirements Eq. (4) are satisfied. Thus the explicit equation of motion of the system is given by [8]

$$M\ddot{q} = Q + A^T(AM^{-1}A^T)^{+}(b - Aa) \tag{6}$$

where + is a Moore-Penrose inverse of the matrix [8]. The control force that the uncontrolled system is subjects to, because of the presence of the control requirements Eq. (4), can be explicitly expressed

$$Q^C = A^T(AM^{-1}A^T)^{+}(b - Aa). \tag{7}$$

The control force given in Eq. (7) is optimized in the sense that it minimizes the control cost $Q^{C^T}M^{-1}Q^C$ at each instant of time. The weighting matrix in the control cost has been chosen to be M^{-1}, although other positive definite matrices can be easily chosen. Pre-multiplying both side of Eq. (6) with M^{-1}, the acceleration of the system that satisfies the constraint Eq. (3) can be expressed as

$$\ddot{q} = a + M^{-1}A^T(AM^{-1}A^T)^{+}(b - Aa). \tag{8}$$

DYNAMICS OF THE UNMANNED GROUND VEHICLE

The design process for 2 Unmanned Ground Vehicles (UGVs) using the Fundamental Equations of Constrained Motion (FECM), which consists of 3 steps (Unconstrained system, Constraint equation, and Constrained system) is hereto discussed.

Unconstrained system

For the dynamics of the UGV system, let two vehicles that are considered as point masses which each has 1000 kilograms move freely in the Cartesian coordinate as seen on Fig. 1.

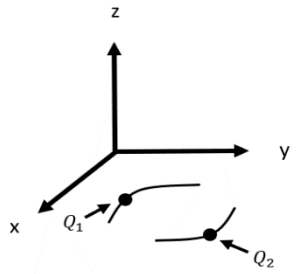

Fig. 1 Planar motion of two vehicles

Using Lagrange's equation, it is described by

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{q}}\right) - \frac{\partial T}{\partial q} + \frac{\partial V}{\partial q} = Q \tag{9}$$

where q is the generalized coordinate, T is the kinetic energy, V is the potential energy, and Q is the generalized force of the system. Whereas we consider

that the vehicles move on a planar motion, so the potential energy of the system is zero. The unconstrained system is considered as

$$M := \begin{bmatrix} m_1 & 0 & 0 & 0 \\ 0 & m_1 & 0 & 0 \\ 0 & 0 & m_2 & 0 \\ 0 & 0 & 0 & m_2 \end{bmatrix} \begin{bmatrix} \ddot{x}_1 \\ \ddot{y}_1 \\ \ddot{x}_2 \\ \ddot{y}_2 \end{bmatrix} = \begin{bmatrix} Q_{x1} \\ Q_{y1} \\ Q_{x2} \\ Q_{y2} \end{bmatrix} := Q \quad (10)$$

where $m_1 = m_2 = 1000$ kg and we assume that there is no applied force to the system, so that $Q_{x1} = Q_{y1} = Q_{x2} = Q_{y2} = 0$.

Constraint Equation

We bring a factory's map to set designated routes by specifying the distance of each square block to be 5 meters wide and 3 meters long and also using time to relate the movements of vehicles in each period as seen on Fig. 2. The red line shows movement of the first vehicle, while the blue one represents that of the second vehicle. The starting point (0,0) of both vehicles is at the top of the warehouse.

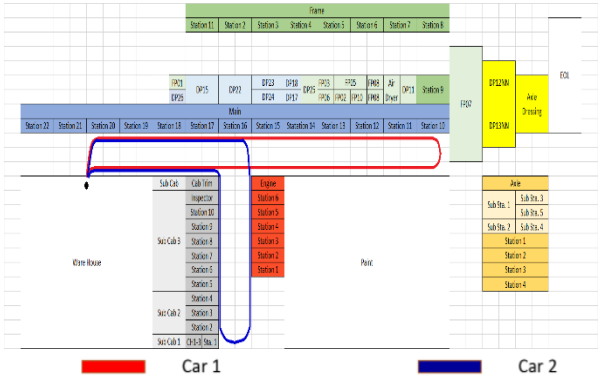

Fig. 2 Factory map and movement path model

For generating constraints of vehicle's movements, we divided motions of the system into 16 periods. And since lengthy limitation is considered, we only illustrate an example of some periods of motions of the two vehicles in this paper. From Fig. 2, we use the vehicle's paths to create the positioning coordinates on x, y graph by Microsoft Excel program and create the path equations of motion for each period as seen on Figs. 3 and 4 for the first and second vehicles respectively.

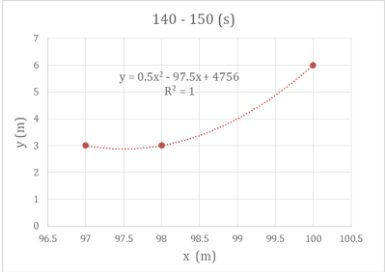

Fig. 3 Motion of the first vehicle at 140 - 150 sec

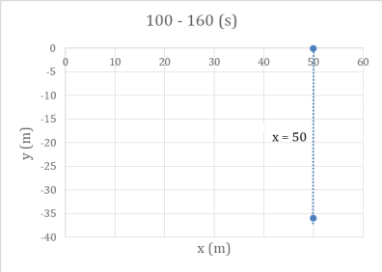

Fig. 4 Motion of the second vehicle at 100 - 160 sec

By appropriately differentiating equations of constraint in Fig. 3 and Fig. 4, they are then used to create path constraint equations in the linear function of acceleration form as

$$\phi_1 := A_1(q, \dot{q}, t)\ddot{q} - b_1(q, \dot{q}, t) = 0 \quad (11)$$

where A_1 is the path constraint matrix and b_1 is the path constraint vector.

Beside the path condition equations, the speed condition equation that is related to time is an aid for the vehicles to run within the specified time limit and allows both vehicles to be related. Such equation is generated from the relationship of time and motion with a linear function

$$x_2 - x_1 = p(t_2 - t_1) \quad (12)$$

where x_i is the displacement in X-axis of vehicle *i*, t_i is the time used of vehicle *i*, and p is the slope of linear relation between x_i and t_i.

Differentiating Eq. (12) twice and put it in the form of the linear function of acceleration as

$$\phi_2 := A_2(q, \dot{q}, t)\ddot{q} - b_2(q, \dot{q}, t) = 0 \quad (13)$$

where A_2 is the time constraint matrix and b_2 is the time constraint vector.

In order to guarantee that both vehicles will move on the designed paths at the right time, the constraint

equations Eq. (11) and Eq. (13) are modified using the Trajectory Stabilization [9].

$$\alpha\ddot{\phi} + \beta\dot{\phi} + \gamma\phi = 0 \quad (14)$$

where $\phi = \begin{bmatrix} \phi_1 & \phi_2 \end{bmatrix}^T$ is the modified constraint function equation and α, β, γ are any positive constants.

Trajectory stabilization can also help finding initial conditions which can be difficult for a complex system that has a large number of conditional equations. The equation will force the function ϕ to approach zero when the time enters to infinity, which results in the system being able to follow the specified conditions.

Here is a concluded procedure of calculations of the constraint equations for the linear functions of acceleration. First, the equations for the movements of various periods are arranged in the form of the Trajectory Stabilization as well as the velocity condition equations associated with time. Second, based on the calculations of the above motion conditions, rearranging the equations to the linear form of acceleration (see Eq. (4)), we then obtain the parameters *A* and *b*, which are the constraint matrix and constraint vector of the constraint equation respectively.

Constrained System

Taking the parameters *M* and *Q* from the unconstrained system and parameters *A* and *b* from the constraint equation to create a controller by the Fundamental Equations of Constrained Motion, we obtain the constrained system.

$$M(q,t)\ddot{q} = Q(q,\dot{q},t) + A^T(AM^{-1}A^T)^+(b - Aa). \quad (15)$$

The obtained controller is then used to calculate on the MATLAB program to verify the accuracy of the movements of both vehicles by using the ODE45 function.

RESULT

ODE45 is the integration procedure using Runge-Kutta method for velocity and displacement of any movements. In calculation, ODE45 function requires 3 parameters which are the acceleration of the constrained motion, time, and initial conditions. When calculated by the ODE45 function, we can check the validity of the designed controller generated from the Fundamental Equations of Constrained Motion.

Experiment and results are analyzed in this section. The results are divided into periods. As written on MATLAB, they consist of 16 ranges, which are divided by relative time of the two vehicles. The first vehicle has a period from 0 - 280 seconds, which is divided into ranges 1 - 14. The second vehicle is set to have a period from 20 - 310 seconds, which is also divided into periods 3 – 16.

The results of the experiments presented include the movements of both vehicles during that control periods, the errors of the movements of the vehicles, the speed conditions associated with the time, and the control forces (constraint forces: Q^C).

As mentioned that there is a page limitation in this paper, we choose to show some examples of the experimental results**.**

Movement of the First Vehicle at 0 - 10 sec

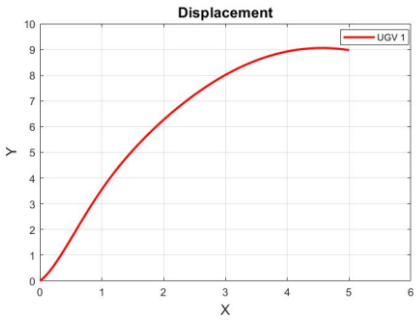

Fig. 5 Moving route of vehicle 1

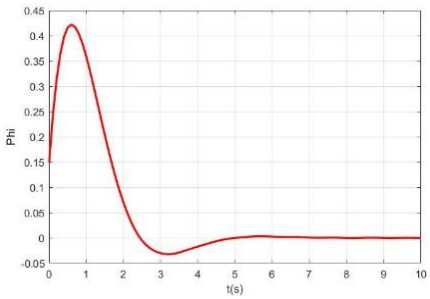

Fig. 6 Error of movement of vehicles 1

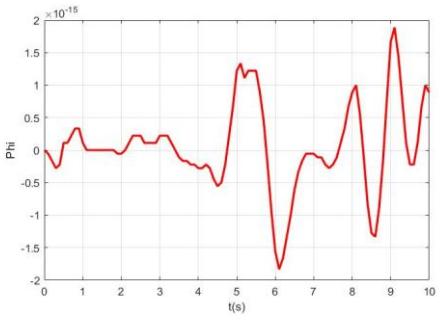

Fig. 7 Error of speed condition of vehicle 1

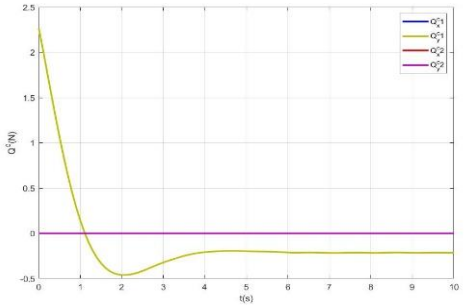

Fig. 8 Effect of Control forces (Q^C)

Movement of the Second Vehicle at 230 - 240 sec

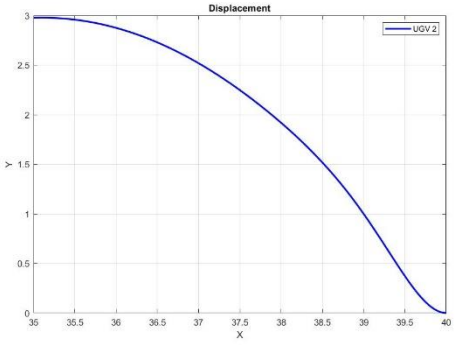

Fig. 9 Moving route of vehicle 2

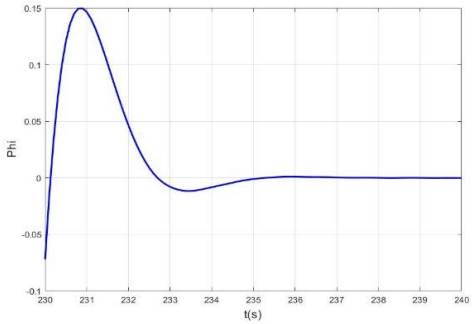

Fig. 10 Error of movement of vehicles 2

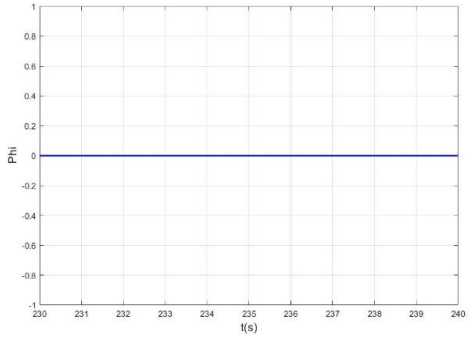

Fig. 11 Error of speed condition of vehicle 2

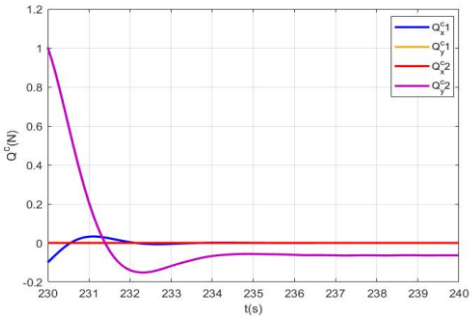

Fig. 12 Effect of control forces (Q^C)

Figures 5 and 9 show path movements of the vehicles 1 and 2 respectively on the X-Y plane. Figures 6 and 10 correspondingly illustrate the errors in tracking the designated routes of vehicles 1 and 2 in their own period. The results of the errors of the speed conditions associated with time of the vehicle 1 and vehicle 2 are presented in Figs. 7 and 11 respectively. All the errors are values that approach zero or into balance. This verifies that even each vehicle of that period has different convergence speeds, but all errors are acceptable values and still make unmanned vehicles able to work efficiently.

The control forces (Q^C) which are shown in Figs. 8 and 12 are the force that help in driving the unmanned ground vehicles to follow the conditions of path tracking and the speed of both vehicles

After creating the graphs in each phase, the entire 16 stages are combined as a result of the movement routes of the two vehicles together as seen on Figs. 13 and 14.

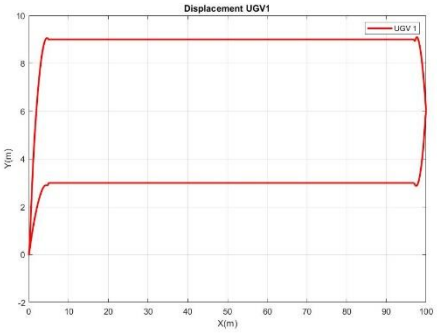

Fig. 13 Moving result on all routes of vehicle 1

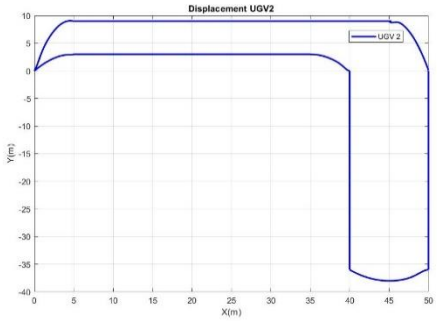

Fig. 14 Moving result on all routes of vehicle 2

Figure 15 displays the total movements of both vehicles which are similar to the one that of shown in the designed factory map in Fig. 2.

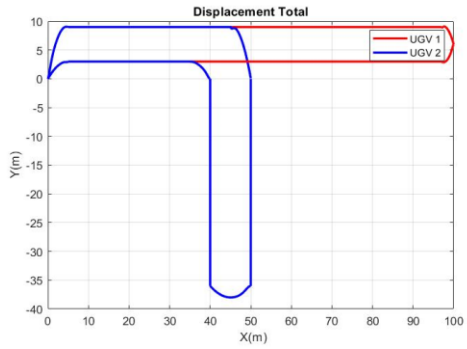

Fig. 15 Moving results of both vehicles

CONCLUSION

It is concluded that the research and experimentation in this work make it possible to see the results that are satisfactory and fulfilled at the intended purpose. Vehicles' movement inspection is done by using ODE45, which is the function in MATLAB program, to inspect the movement positioning' s data. The processes show that the control forces, which this research found from the Fundamental Equations of Constrained Motion, guarantee the movements of the vehicles. The errors of movements of both vehicles are very low and are satisfying. Moreover, the size of the errors and the speed in approaching stability can be controlled with the flexibility in choosing the proposed control parameters. We thus see that in the future, if the proposed controller is to be developed more or less, such as considering uncertainty in the system, we believe and hope that the proposed control system can actually be used in controlling movements of any vehicles in the real industrial factories.

ACKNOWLEDGEMENT

We would like to thank Dr. Thanapat Wanichanon for providing advice and assistance in this work. We also thank to the administrative staffs of the Department of Mechanical Engineering for providing all useful facilities. We also thank friends for both physical and mental support. Finally, we would like to thank to the faculty members of the Faculty of Engineering at Mahidol University, who convey various knowledge, as a result, there is a driving force for this work. The authors hope that this work will help to understand the stability control of unmanned vehicles in tracking system. For those who are interested, this work is a guideline for further system development and applying technology.

SPATIAL ESTIMATION OF CADMIUM CONTAMINATED SEDIMENT FROM THE UPSTREAM OF THE REMOTE CONTAMINATED AREA OF THE MAE TAO BASIN, THAILAND

Sinsantithet M.[1], Somprasong K.[2]
[1,2]Department of Mining and Engineering, Faculty of Engineering,
Chiang Mai University, Thailand

ABSTRACT

Overland sediment, occurred during rainfall incident, has been verified as one of the transcendent media transporters of cadmium contaminant in the Mae Tao Basin, Thailand since 2011. The integrated spatial approach based on the Revised Universal Soil Loss Equation (RUSLE) was applied for illustrating the area where a high volume of cadmium can be leached out with acceptable precision. However, this estimation technique, is subjected to the inclusiveness of the secondary data, applied as inputs in the calculation. In order to overwhelm this limitation, the alternate integrated spatial procedure should be applied for the better estimation's results, compared to the previous one. In this study, the Revised Morgan-Morgan and Finney erosion model (RMMF) was applied with the purpose of overwhelming the limitation in utilizing secondary data. The RMMF model can reflect both of erosion potential of the monitoring area and the sediment transportation capacity after the occurrences of the erosion. As stated by RMMF, which is based on the interaction of kinetic energy from the contact between rainfall intensity and the specific soil surface. Consistent with the estimation's results, the potential erosion of the downstream area of the basin were ranged from 6.22 to 99.346 t/ha/year. In order to compare the efficiency of this method to the previous RUSLE, the potential cadmium fluxes from erosion of the same area, from 2006 to 2009, were analyzed, using the relative standard error. The results indicate that RMMF can perform better %RSD to the previous RUSLE ranged from 4.204 to 16.550.
Keywords: Erosion, GIS, RMMF, Spatial technologies, Contamination

INTRODUCTION

The Mae Tao basin is a large important basin of Mae Sot district, Tak, Thailand. The development of the area for the expansion of agricultural lands is necessary in order to support the population growth of the area nearby. This situation can cause a major change in land use resulting as the alternation of factors that contribute to soil erosion, such as rainfall runoff, soil erodibility and plant canopy. Soil erosion can cause a migration of heavy metal contaminants through sediment transport and sediment accumulation over the watershed area especially cadmium, born in association with zinc - deposition [1].

The Revised Universal Soil Loss Equation (RUSLE) erosion model has developed to replace the USLE and incorporates new material. It has been widely applied as an accommodating equation for estimating surface erosion by requiring less data and necessitating a short period of time to run compared to other erosion estimation [1]. The model propagates estimated soil loss through increasing the parameter of rainfall erosivity, soil erodibility, slope gradient and length, cover management and confirmation practice. This makes RUSLE a consequence of topography model which is a consideration for the slope length multiplier. According to the study of [2] which applied the RUSLE equation with remote sensing technique and geographic information system (GIS) technology the amount of potential cadmium flux from erosion was 279.86 to 703.73 t/ha/year in 2002-2016. Although, RUSLE can be an effective tool for the estimation of potential flux that can be occurred during rainfall's erosion, thus the model itself cannot exemplify the plausible quantity of sediment's migration. It is subjected to the inclusiveness of the secondary data, applied as inputs in the calculation especially the correctness of the elevation map applied during model construction. In order to overwhelm this limitation, alternate integrated spatial procedure should be applied for the better estimation's results, compared to the previous one.

While RUSLE is the empirical estimation for potential soil loss of the area, the application of Revised Morgan-Morgan and Finney (RMMF) erosion model was developed to suits annual soil loss in hill slope [3]. This model is divided into two phases, the water phase, and the sediment phase. The water phase determines the energy of the rainfall available to detach soil particle from soil mass and the volume of runoff. In the sediment phase, rate of soil particle detachment by rainfall runoff is determined along with transporting capacity of [4].

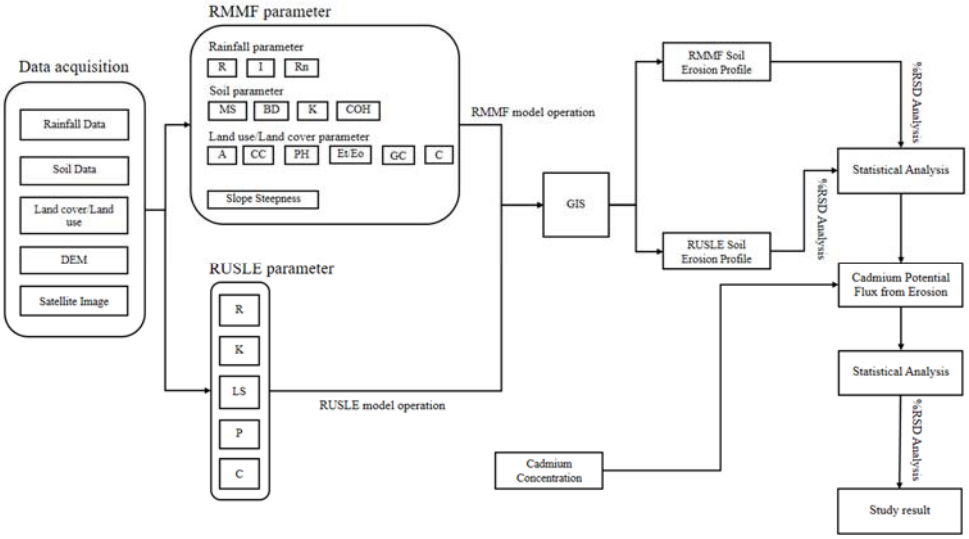

Figure 1. Overall framework of the study

In this study, the RMMF model is applied in association with remote sensing technique and geographic information system (GIS) to estimate soil loss in the Mae Tao basin. Data inputs of the RMMF model were provided in a geographic information system (GIS) which is consisted of spatial data linked to the attribute data. The process is creating data as a parameter map by using interpolation and the data were collected in raster files. The result of annual soil loss rate in the form of raster data, retrieved from RMMF model were used to conduct the contamination assessment by integrating it with cadmium concentration layer. The estimation's results from RMMF model were compared with the results of the RUSLE model, according to the study of [2]. In order to elucidate the efficiency of each estimation's method, relative standard error analysis of the same monitoring area was accomplished.

METHODOLOGY

The overall framework of this study is demonstrated in Fig.1 The study instigated with data acquisition. The secondary data from various sources were gathered to be assigned as the RMMF 's inputs. The model computes the proportion of rainfall amount that reaches the ground surface after allowing for the interception to derive effect rainfall. It is further distributed into two parts. First, rainfall that reached the ground surface after being intercept by plant canopy as leaf drainage and another part is the rainfall without an interception. Then the kinetic energy is calculated by the difference of direct through fall and leaf drainage. The annual runoff is calculated by using three parameters including soil moisture storage capacity, annual rainfall and mean rainy days. The soil moisture storage capacity is a function of bulk density, effective hydrological depth, a ratio of actual to potential evaporation and soil moisture content at field capacity. The estimation of soil particle detachment by raindrop and runoff are divided into two part. The soil particle detachment by a raindrop is a combination of the total kinetic energy of rainfall and soil erodibility. The calculation of detachment by runoff is a function of runoff, soil resistance, ground cover, and slope steepness. Total detachment is as a sum of both soil particle detachment by raindrop and runoff. The transport capacity is estimated by using runoff, surface cover factor, and slope. To obtain annual soil loss prediction, the RMMF model compares the total detachment and transport capacity for each grid and the minimum erosion rate is selected as the estimation of annual soil loss. The result of annual soil loss from the RUSLE model is obtained from the study of [2]. The cadmium potential flux from erosion is computed by using cadmium profile and annual soil loss. Finally, the annual soil loss and potential cadmium flux from the RMMF method is compared with the result of the RUSLE model by using a statistical analysis technique as relative standard deviation (%RSD).

Site Description

The Mae Tao Basin described as the largest zinc deposition area of Thailand. The basin covers 59.61 km^2, as can be followed in Fig.2. The basin contains 4 main significant land use type which are rice paddy field, mining production area, cornfield and deciduous forest [4]. The contamination over the Mae Tao Basin has been widely spread and was mostly detected to exceed the acceptable standards [5].

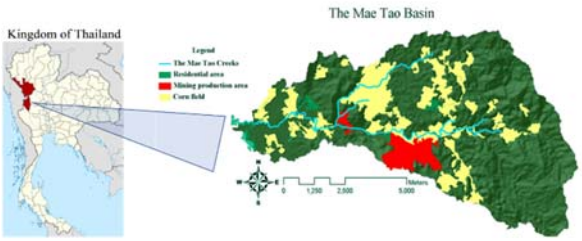

Fig. 2 Location of the Mae Tao Basin [1]

Data acquisition

All input data were prepared at a 30 m resolution. The Rainfall data were obtained from The Thai Meteorological Department, with a 5 km spatial resolution. Rainfall data is interpolated on the model grid using IDW interpolation. Soil textural fractions (sand, clay, and silt) and soil organic matter content are obtained from The Land Development Department (LDD). The land use data are obtained from The Land Development Department (LDD) at 30 m resolution. A digital elevation model was obtained from the Royal Thai Survey Department (RTSD). The satellite image of the basin, covering the study period from 2002-2016 were afforded by GISTDA.

Integrated RUSLE Estimation

The revised universal soil loss equation (RUSLE) is an empirical model, modified from the USLE [6]. It estimates sheet and rill erosion using Eq.1. Since cadmium, contaminated in the basin adsorb with the overland sediment as residue from surface runoff (Somprasong et.al, 2015), so the RUSLE can effectively estimate the fluxes of the contamination migrated over the study area [1].In this study, the results from integrated RUSLE estimation were referenced from [2].

$$A = R \times K \times LS \times C \times P \quad (1)$$

Revised Morgan – Morgan and Finney Model

RMMF model is developed from the MMF physical model that divides the erosion process into 2 phases which are the water phase and the sediment phase. The water phase is calculated by using the evaluation of kinetic energy from rainfall and runoff. The sediment phase consists of the estimation of soil particle detachment by raindrop and runoff along with the runoff's transporting capacity [4].

Different from the MMF, the simulation of soil particle detachment by raindrop takes a parameter of plant canopy height and leaf drainage and a component has been added for soil particle detachment by the flow, while estimation of soil erosion is computed by comparing total soil particle detachment and transport capacity of runoff.

Estimation of Rainfall Energy

Rainfall energy, determined by RMMF, is a function of the difference between kinetic energy of direct through fall and kinetic energy of leaf drainage. First, the model computes the proportion of rainfall amount that reaches the ground surface after deducting for rainfall interception as effective rainfall. as presented in (6).

$$ER = R \times A \quad (6)$$

R indicates annual rainfall (mm), while A refers to rainfall interception value range from 0 to 1 based on the study of [6] According to RMMF, effective rainfall is divided into direct through fall (DT, mm) and leaf drainage (LD, mm). Leaf drainage is a function of effective rainfall and canopy cover. The leaf drainage can be retrieved from (7), while direct through fall is calculated by (8) respectively.

$$LD = ER \times CC \quad (7)$$

$$DT = ER - LD \quad (8)$$

The kinetic energy of direct through fall can be calculated by distribution of the effective rainfall intensity on leaf drainage and direct through fall, whereas kinetic energy of leaf drainage is a function of plant height, the kinetic energy of direct through fall is presented in (9) and the kinetic energy of leaf drainage is according to (10).

$$KE(DT) = DT(11.9 + 8.7\, log\, I) \quad (9)$$

$$KE(LD) = LD(1.58 \times PH^{0.5}) - 5.87 \quad (10)$$

Where KE (DT) is kinetic energy of direct through fall (j/m^2), I represents the rainfall intensity, KE (LD) stands for the kinetic energy of leaf drainage (j/m^2) and PH is plant height (m). The total kinetic energy (KE_{total} (j/m^2)), is obtained from (11)

$$KE_{total} = KE(DT) - KE(LD) \quad (11)$$

Estimation of Rainfall Runoff

Runoff can be calculated, using three factors consist of soil moisture storage capacity, annual rainfall and mean rainy days. Equation (12) expresses the calculation of soil moisture storage capacity.

$$R_C = 1000 \times MS \times BD \times EHD \times (E_t/E_0) \quad (12)$$

As stated by the equation, MS stands for soil moisture content at the field, BD is expressed as the density of the topsoil layer (Mg/m^3) and EHD is an effective hydrological depth of rainfall. E_t/E_o refers to the ratio of actual evapotranspiration to potential transpiration of the cover plant over the monitoring area

For mean rainy days, the calculation can be retrieved from (13), where R and R_n indicates annual rainfall (mm) and numbers of rainy days in a year respectively.

$$R_0 = R/R_n \quad (13)$$

Estimation soil particle detachment by raindrop and runoff

The estimation of soil particle detachment is divided in two part. First, the soil particle detachment by a raindrop is derived from the combination between total kinetic energy and soil erodibility parameter are applied following Eq. (14).

$$F = K \times KE_{total} \times 10^{-3} \quad (14)$$

Where K indicate soil erodibility (g/j) which is a unique characteristic of each soil types. The soil detachment by runoff can be derived from surface cohesion slope steepness (degree) and ground as can be followed in Eq.15 and Eq.16.

$$Z = 1/(0.5COH) \quad (15)$$

$$H = Z \times Q^{1.5} \times sin\, S \times (1 - GC) \times 10^{-3} \quad (16)$$

Where Z refers to the soil resistance. COH is the surface cohesion (kpa) that can be follow in Table 1. Total particle detachment (D, kg/m^2) is finally calculated as a sum of both soil particle detachment by raindrop and runoff. The calculation is presented in (17).

$$D = F + H \quad (17)$$

Table 1 demonstrates the input parameters, applied as soil properties in the estimation of this study

Table 1 Input parameters of soil properties

Soil Texture	K (gJ^{-1})	MS ($\%ww^{-1}$)	BD (mg^{-3})	COH (KPa)
Clay	0.05	0.45	1.10	12
Clay loam	0.70	0.40	1.30	10
Silty clay	0.50	0.30	-	10
Sandy loam	0.70	0.28	1.20	2
Silt loam	0.70	0.25	1.30	3
Loam	0.80	0.20	1.30	3
Fine sand	1.00	0.15	1.40	3
Sand	1.20	0.08	1.50	2

Estimation of transport capacity of runoff

The transport capacity of runoff can be retrieved from (18)

$$\mathrm{TC} = \mathrm{C} \times \mathrm{Q}^2 \times \sin \mathrm{S} \times 10^{-3} \quad (18)$$

C is the crop or plant cover factor. Q refers to annual runoff (mm). TC stands for the transport capacity of the runoff (g/m^2) S is slope angle of the monitoring area (degree). This is then compared with the annual transport capacity and the lesser of the two values is the annual erosion rate [7].

Table 2 Input parameter of land use/land cover data

Land cover	A (gJ^{-1})	E_t/E_o ($\%ww^{-1}$)	C (mg^{3})	EHD (KPa)
Paddy field	0.25	0.60	0.525	0.12
crop	0.25	0.60	0.525	0.12
Grassland	0.20	0.88	0.1	0.14
Perennial	0.20	0.90	0.3	0.15
Orchard	0.20	0.70	0.3	0.15
Forest	0.30	0.90	0.048	0.2
Mine	0	0.05	0	0.05
Village	0	0	0	0

Table 3 Input parameter of land use/land cover data (Cont.)

Land cover	CC (gJ^{-1})	GC ($\%ww^{-1}$)	PH (mg^{-3})
Paddy field	0.49	0.37	1.8
crop	0.49	0.37	1.8
Grassland	0.93	0.95	1.5
Perennial	0.49	0.37	1.8
Orchard	0.31	0.5	7.3
Forest	0.81	0.91	19.4
Mine	0	0	0
Village	0	0	0

Estimation of erosion in turn of soil loss rate

Soil loss rate is generated by comparing between total soil particle detachment and transport capacity of runoff. The minimum value is applied following the last step in the script. For the calculation of soil loss (SL) rate is computed by using equation (19).

$$\mathrm{SL} = \min\{\mathrm{D}, \mathrm{TC}\} \quad (19)$$

Potential cadmium flux from erosion estimation and comparison

The estimation of potential cadmium contamination fluxes over the basin can be achieved according to Eq. (20).

$$\mathrm{PE} = [\mathrm{Cd}] \times \mathrm{SL} \quad (20)$$

Where, PE is the potential availability of cadmium. [Cd] stands for the cadmium concentration of the monitoring area in form of calculation layer in GIS application. The potential cadmium flux from erosion, obtained from both methods were analyzed using relative standard deviation formula following [1],[9].

RESULTS & DISCUSSION

The potential erosion of the Mae Tao basin, estimated using RMMF, are established in Table 3. The highest potential erosion was determined to be 99.346 ± 3.502 t/ha/y at the downstream of the basin in 2009. The soil loss map then was classified into erosion prone area, determined according to the threshold values from [8] The tolerance of soil loss rate that agriculturist should be concern was more than 10 ton/ha/year [4] The potential erosion map of the Mae Tao Basin is shown in Table 5 and Fig.3 According to the estimation results, the erosion occurred upon the study area were mostly determined to be very slight class.

Table 4. Estimation results from the RMMF's estimations

Year	Potential Erosion (t/ha/y)			
	Minimum	Mean	Maximum	SD
2006	0	41.11	82.22	3.118
2009	0	49.67	99.35	3.520
2012	0	3.11	6.22	0.771
2016	0	42.46	92.85	2.687

Table 5 demonstrates the potential cadmium flux from erosion of the Mae Tao Basin, based on the calculation of both methods. For RUSLE, the highest value of potential cadmium flux from erosion was found to be 687 t/ha/y, while 3.42 t/ha/y were determined to be the highest value of the contamination's fluxes from the estimation using RMMF model.

Table 5. Potential cadmium flux from erosion, obtained from RUSLE and RMMF

Year	Potential cadmium Fluxes from erosion (t/ha/y)		Relative standard deviation (RSD) (%)	
	RUSLE	RMMF	RUSLE	RMMF
2006	687.5	3.42	381.11	15.98
2009	142	0.73	355.21	16.55
2012	62.02	0.29	274.12	4.2
2016	32.5	0.94	385.02	15.73

Even supposing that the results from RMMF demonstrate the lower value than the those, obtained from RUSLE, but only the pixels value cannot represent the quality of the estimation so that relative standard deviation analysis was then conducted.

According to the analytical outcomes, the %RSD of RMMF ranges from 4.20 to 16.55 % while 274.12 to 385.02. As smaller % RSD represents the better value of precision and consistency of the estimation, RMMF, based on the combination between real field observation and detailed recorded data, can perform better precision in the determination of the distribution of cadmium contamination from erosion.

As stated by the estimation results, the estimation, using RMMF, contains better results. Since its calculation method is mostly subjected to the rainfall intensity data, which is classified as primary data, so there are less interferences from the initial errors of the data input, compared to the previous integrated model. Furthermore, since the calculation method of RMMF model is based on the actual interaction between rainfall and soil surface, therefore hydrological properties, soil surface and plant cover properties are integrated, resulting in better precision of the estimations.

To achieve better estimation's results for migration availability, the enhancement of the assigned parameter such as cadmium concentration profile should be conduct. Although the estimation's results of RMMF can perform better precision thus the gathering all data required in the erosion model is limited. Therefore, most of the parameters' values used in the erosion model were acquired from literature which may cause uncertainty on the results. To overwhelm this limitation, the direct field measurement must be conducted in the reachable area of the basin to elucidate the performance of the RMMF model 'estimation.

Conclusion

In conclusion, it appears that RMMF model can be efficiently used as tools to assess the severities for soil degradation evaluation. By accounting real interaction between rainfall and soil surface during rainfall incident, the model can give better precision than the previously proposed integrated RUSLE estimation. Even though the result of estimation of soil erosion may not be according to the exact value, but this result can illustrate the potential migration availability of the contaminant over the study area, therefore, more field measurement is recommended for the other parameter in order to achieve the realistic model results.

STABILITY ANALYSIS OF AN ACTIVE VEHICLE SUSPENSION SYSTEM

ThanapatWanichanon[1], ChayadaThidrasamee[2] , Thana Pornrattanaprasert[3], and Palita Mahachotikul[4]
[1.2.3.4]Faculty of Engineering, Mahidol University, Thailand

ABSTRACT

A car suspension is widely applied due to its use in smoothening a car when driving or absorbance of impacts made to the car. With its usefulness, developments and creations of new suspensions are being continuously conducted. This results in having better experience with less impact when driving from rough road for drivers and passengers.

This work conducts a research in developing an active suspension by analyzing a working process of a car suspension using the fundamental equations of constrained motion and Lyapunov theory. MATLAB software is used in the analyzing process and to examine the correctness of the results.

With the research conducted, the analysis found that the results from the analyzing process set to the satisfaction. The work is also completed according to the objectives and limitations which are successful in finding a mathematical model for the design and controller of the active suspension in a car. This also includes the ability to analyze functions of the controller and it is found that spring constant of choke, spring constant of tire and damping constant affect smoothness of a car suspension.

Keywords:Stability, Suspension system, The fundamental equation, Constrained motion

INTRODUCTION

Nowadays, smooth driving is the main objective in developing modern cars and is one of the significant key satisfactions of customers. If cars have a suspension with better response to the roads, passengers will have better satisfaction towards those particular cars. The suspension that is currently favored for further development is an Active Suspension [3]-[5]. This dues to its ability to constantly adjust the force applied to the suspension system by calculating suitable forces for each kind of roads at any period of time. In the model of study it is assumed that the suspension could apply forces to both sprung mass and unsprung mass, which are comparable to a car cabin and a car suspension respectively. As in many references of researches related to the active suspension [1]-[2], it is easier to consider a dynamic model of a quarter car and control the system with feedback controller [6]-[7]. With that, if errors were to be found, the controller will try to correct the system back to the equilibrium point. In this paper, the fundamental equations of constrained motion is used to solve the dynamic equations of the mathematical model for a quarter car in order to verify that the controller could perform according to the stability's criterions [8]. In addition, Lyapunov theory is applied in the process of determining the stability constraint of the system. The linear constraint function in the form of acceleration is then received. Its condition helps diminishing the energies in the system to be zero or close to the equilibrium point, which meets the designed expectation. The verification of the effectiveness of the proposed controller is done by a numerical computation in MATLAB to find the displacement and velocity in each period of time of the sprung and unsprung masses of the quarter car. This is to prove that the system meets the stability's expectations and designed objectives.

DYNAMICS

On the dynamics we analyze our interested system by using the fundamental equations of constrained motion. The approach is divided into three steps.

Unconstrained System

First, Newton second law of motion is used to create unconstrained motion's equation to find a non-constrained system's equation.

$$\sum F = ma. \tag{1}$$

Equation (1) can be written as

$$M\ddot{q} = Q \tag{2}$$

where

M is a mass matrix (kg)
$\ddot{q}$ is a generalized acceleration ($\mathrm{m/s^2}$)
Q is a generalized force (N).

Pre multiplying Eq. (2) with M^{-1}, we can find the unconstrained system's acceleration as

$$a := \ddot{q} = M^{-1}Q\,. \tag{3}$$

Constraint Equation

For this part, a constraint (or a part which forces the system back to a desired stage) is defined for the system to be back to the equilibrium

$$\phi(q,\dot{q},t) = 0\,. \tag{4}$$

Differentiating Eq. (4) and rewriting it in an acceleration form, we have

$$A(q,\dot{q},t)\ddot{q} = b(q,\dot{q},t) \tag{5}$$

where

A is a constraint matrix
b is a constant vector.

Constrained System

In order the system to satisfy the constraint (5), from the Newton second law of motion (Eq. (2)), we add forces from feedback controller as a control force.

$$M\ddot{q} = Q(q,\dot{q},t) + Q^C(q,\dot{q},t) \tag{6}$$

where

Q^C is a control force (N), which is computed from Ref. [11] as

$$Q^C = A^T(AM^{-1}A^T)^+(b - A\ddot{q}) \tag{7}$$

where

+ is the Moore-Penrose inverse of the matrix [8].

Then substituting Eq. (7) into Eq. (6) and pre-multiplying the equation with M^{-1}, we finally get the dynamic equations in the form of acceleration

$$\ddot{q} = a + M^{-1}A^T(AM^{-1}A^T)^+(b - Aa). \tag{8}$$

In order to verify motions of the constrained system, we integrated Eq. (8) twice to compute velocity and displacement of the system respectively in any period of time.

METHOLOGY

Analyzing the Unconstrained System

In this work a quarter car is modeled with an active suspension as seen in Fig. 1. In its free body diagram a vertical movement of a two-degree of freedom system of sprung and unsprung masses is considered. By the virtue of the unconstrained motion, the Newton second law of motion [1] yields mathematical models of the system without any control force from hydraulic (Q^c) (see Eq. (2)):

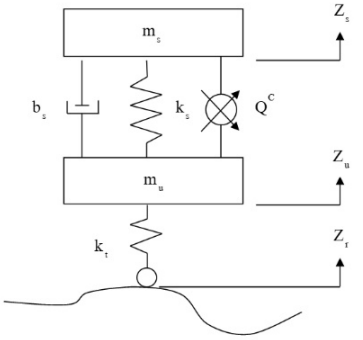

Fig. 1 Quarter car

For sprung mass

$$m_s\ddot{z}_s = -k_s(z_s - z_u) - b_s(\dot{z}_s - \dot{z}_u) \tag{9}$$

and for unsprung mass

$$m_u\ddot{z}_u = k_s(z_s - z_u) + b_s(\dot{z}_s - \dot{z}_u) + k_t(z_r - z_u) \tag{10}$$

where

m_s is sprung mass (kg)
m_u is unsprung mass (kg)
z_s is displacement of sprung mass (m)
z_u is displacement of unsprung mass (m)
$\dot{z}_s$ is velocity of sprung mass (m/s)
$\dot{z}_u$ is velocity of unsprung mass (m/s)
k_s is spring constant of sprung mass (N/m)
b_s is damping constant of sprung mass(Ns/m)
k_t is spring constant of tire (N/m)
z_r is displacement from road (m).

Rearranging Eqs. (9) and (10) into a matrix form, we obtain

$$\begin{bmatrix} m_s & 0 \\ 0 & m_u \end{bmatrix}\begin{bmatrix} \ddot{z}_s \\ \ddot{z}_u \end{bmatrix}=\begin{bmatrix} k_s(z_u-z_s)+b_s(\dot{z}_u-\dot{z}_s) \\ k_s(z_s-z_u)+b_s(\dot{z}_s-\dot{z}_u)+k_t(z_r-z_u) \end{bmatrix}. \tag{11}$$

The matrix in front of the acceleration is considered as the mass matrix (*M*) and another one on the right handed side of the equation is the generalized force vector (*Q*). So we get these two parameters of the unconstrained system

$$M(q,t):=\begin{bmatrix} m_s & 0 \\ 0 & m_u \end{bmatrix}$$

$$Q(q,\dot{q},t):=\begin{bmatrix} k_s(z_u-z_s)+b_s(\dot{z}_u-\dot{z}_s) \\ k_s(z_s-z_u)+b_s(\dot{z}_s-\dot{z}_u)+k_t(z_r-z_u) \end{bmatrix}. \tag{12}$$

Assigning a Constraint Equation

This step is to define a function that controls the system. Let us begin with the constraint equation from Eq. (4). Since stability of the movements of the sprung and unsprung masses are considered, Lyapunov stability criterion is used in this work [7].

Now let us talk about Lyapunov stability criterion. It composes of a function of V, which is also known as Lyapunov candidate function. In our work, we assume that it is a function of displacement, velocity and time. Stability in Lyapunov sense is satisfied with two conditions

1. *A positive definite function of the Lyapunov candidate*

$$V(q,\dot{q},t)>0. \tag{13}$$

2. *Differentiation of the Lyapunov candidate is negative definite function*

$$\frac{d}{dt}(V(q,\dot{q},t))<0. \tag{14}$$

To satisfy the first condition is not a challenge. However, in order to find a positive definite function that also has negative definite differential function is not an ease. We thus consider any positive definite function V that satisfies

$$\dot{V}(q,\dot{q},\ddot{q},t)=-\alpha V(q,\dot{q},t) \tag{15}$$

as a constraint.

In Eq. (15), V is a Lyapunov candidate which is a function of generalized coordinate, generalized velocity and time. α is a positive constant parameter which is to show the speed in which the system can be back to equilibrium.

Our goal is to reduce and bring back displacement and velocity of the sprung and unsprung masses into equilibrium. To prove that this constraint equation suits with the goal, we solve the Eq. (15) so we can get the solution of this equation as

$$V=e^{-\alpha t}V_0. \tag{16}$$

This equation is in the form of an exponential decay. When the time goes to ∞. The function will bring V back to zero. So the parameters that are defined as the function of V is also brought back to zero, which is our equilibrium.

In our case, we use the Lyapunov candidate function [7] as

$$V=\frac{1}{2}a_1q^Tq+\frac{1}{2}a_2v^Tv+a_{12}q^Tv \tag{17}$$

where a_1, a_2, a_{12} are positive constants that satisfy

$$a_1>0,\ a_2>0,\ 0<a_{12}<\sqrt{a_1a_2}, \text{ and}$$

$$\alpha=\frac{2a_{12}}{a_2} \text{ (see Eq. (15))}$$

$$q:=\begin{bmatrix} z_s \\ z_u \end{bmatrix},\ v:=\dot{q}:=\begin{bmatrix} \dot{z}_s \\ \dot{z}_u \end{bmatrix},\ a:=\ddot{q}:=\begin{bmatrix} \ddot{z}_s \\ \ddot{z}_u \end{bmatrix},$$

q is the generalized displacement, v is the generalized velocity, and a is the generalized acceleration.

The derivatives of Eq. (17) is

$$\begin{aligned}\dot{V}=&a_1\begin{bmatrix} z_s & z_u \end{bmatrix}\begin{bmatrix} \dot{z}_s \\ \dot{z}_u \end{bmatrix}+a_2\begin{bmatrix} \dot{z}_s & \dot{z}_u \end{bmatrix}\begin{bmatrix} \ddot{z}_s \\ \ddot{z}_u \end{bmatrix}\\ &+a_{12}\begin{bmatrix} \dot{z}_s & \dot{z}_u \end{bmatrix}\begin{bmatrix} \dot{z}_s \\ \dot{z}_u \end{bmatrix}+a_{12}\begin{bmatrix} z_s & z_u \end{bmatrix}\begin{bmatrix} \ddot{z}_s \\ \ddot{z}_u \end{bmatrix}.\end{aligned} \tag{18}$$

From this part we substitute Eq. (17) and Eq. (18) into Eq. (15)

$$a_1\begin{bmatrix} z_s & z_u \end{bmatrix}\begin{bmatrix} \dot{z}_s \\ \dot{z}_u \end{bmatrix} + a_2\begin{bmatrix} \dot{z}_s & \dot{z}_u \end{bmatrix}\begin{bmatrix} \ddot{z}_s \\ \ddot{z}_u \end{bmatrix}$$
$$+a_{12}\begin{bmatrix} \dot{z}_s & \dot{z}_u \end{bmatrix}\begin{bmatrix} \dot{z}_s \\ \dot{z}_u \end{bmatrix} + a_{12}\begin{bmatrix} z_s & z_u \end{bmatrix}\begin{bmatrix} \ddot{z}_s \\ \ddot{z}_u \end{bmatrix} = -\alpha V. \quad (19)$$

Rearranging Eq. (19) into the acceleration form (see Eq. (5)), we have

$$\begin{bmatrix} a_2\dot{z}_s + a_{12}z_s & 0 \\ 0 & a_2\dot{z}_u + a_{12}z_u \end{bmatrix}\begin{bmatrix} \ddot{z}_s \\ \ddot{z}_u \end{bmatrix}$$
$$= -\left(a_1 z_s \dot{z}_s + a_1 z_u \dot{z}_u + a_{12}\dot{z}_s{}^2 + a_{12}\dot{z}_u{}^2\right) - \alpha V. \quad (20)$$

From Eq. (20) we can find parameter *A* and *b* which are the constraint matrix and the constraint vector respectively as

$$A := \begin{bmatrix} a_2\dot{z}_s + a_{12}z_s & 0 \\ 0 & a_2\dot{z}_u + a_{12}z_u \end{bmatrix}$$
$$b := -\left(a_1 z_s \dot{z}_s + a_1 z_u \dot{z}_u + a_{12}\dot{z}_s{}^2 + a_{12}\dot{z}_u{}^2\right) - \alpha V. \quad (21)$$

Computing Control Forces of the Constrained System

Substituting *M*, *Q* from the unconstrained system and *A*, *b* from the constraint equation in Eqs. (6) and (7). The dynamic equation of our constrained suspension system with control forces is

$$M\ddot{q} = Q(q,\dot{q},t) + A^T(AM^{-1}A^T)^+(b - Aa). \quad (22)$$

After we get the dynamic equation of the constrained system. We could verify its displacement and velocity in any period of time by using MATLAB to compute and validate the result.

RESULT

Consider parameters of the system and the controller as m_s = 208 kg, m_u = 28 kg, k_s = 18709 N/m, k_t = 127200 N/m, b_s = 1300 Ns/m, a_1 = 1, a_2 = 8, a_{12} = 1, and $\alpha = 1/4$.

Given the system mathematical model, consider that both masses have separate equilibrium points related to CG of their particular masses. In the experiment, the values of a_1, a_2, a_{12}, and α are varied until the suitable values are found. In the simulation, the values of the initial conditions of the system are defined as z_s = 0, z_u =0, $\dot{z}_s$ = 0.01, and $\dot{z}_u$ = 0.05. These values are assumed and might not be the correct initial values that are related to the constraint equation of the system. Therefore, the nonlinear solver *fsolve* command in MATLAB is used to solve for the right initial conditions of the non-linear system. We found that the initial conditions that are met with the constraint equation are z_s = -0.0028, z_u = -0.0140, $\dot{z}_s$ = 0.0014, and $\dot{z}_u$ = 0.0070.

In this work we have tested the proposed active suspension controller with three types of road:

1. A sinusoidal wave road with the height of slope equals to 0.075 meters and frequency equals to 0.242 Hz (see Fig. 2). This model represents for a normal road condition.
2. A sinusoidal wave road with natural frequency with the height of slope equals to 0.015 meters and frequency equals to 0.625 Hz, which is the value of natural frequency of the system (see Fig. 5). This case shows the model that has the least suitable frequency for the car of our system.
3. A random road with all random height of the slope and frequency by MATLAB function *rand* (see Fig. 8). This is the example model of an unexpected road type.

The results in the paper only show for displacements of the sprung mass from each road types (see Figs. 3, 6, and 9) which are comparable to the trembling in the car cabin and the additional control forces (see Figs 4, 7, and 10) which negate with the given forces of the system.

Figure 3, 6, and 9 show that the sprung mass which is considered as a car cabin goes back to the equilibrium set point within a short period of time. While Figs. 4, 7, and 10 verify the possibility in generating our control forces.

If the force which controls the system is close to the force generated by the system, it could be a possibility in which we could control the system using the calculated control force.

CONCLUSIONS

In this work the fundamental equations of constrained motion is applied with a quarter active suspension car. We use Lyapunov theory in part of the constraint equation because this theory is based on reducing energy of the system to the equilibrium or zero. We thus finally get the dynamic equation of the constrained system. Then the results are verified by computing the dynamic constrained equation on MATLAB. As the expectation that displacements of the sprung mass and unsprung mass could be brought back to the equilibrium, the results shown verify that the system could do our expectation. Moreover with the experimentation we found that we could adjust the speed that the system goes to the equilibrium by varying the constant parameter α . The greater of α makes the system back to equilibrium faster but the control forces (Q^C) might increase respectively to α. The bigger control force from the generalized force, the less opportunity to succeed in applying the physical part to the suspension system.

Reducing and bringing back the displacement of the system to equilibrium point using the fundamental equations of constrained motion is the way to improve the stability of the suspension. According to the results, we can bring back the car cabin to the equilibrium as we expect. So it is possible that this system could be applied in a real car but it needs further research on the study of physical equipment.

ACKNOWLEDGMENTS

Firstly, I would like to express my sincere gratitude to my advisor Dr. Thanapat Wanichanon for the continuous support of my work and related research, I could not have imagined having a better advisor and mentor for my study.

Besides my advisor, I would like to thank the rest of my thesis committee: Dr. Ittichote Chuckpaiwong, and Dr.Chokchai Chutakositkanon, for the hard questions which incented me to widen my research from various perspectives.

Finally, I must express my very profound gratitude to my parents and to my wonderful faculty members for providing me with support.

STUDY ON LAND SURFACE EMISSIVITY ESTIMATION OVER EAST ASIA

Nozomu Hirose[1], Kenji Taniguchi[2] and Ichiro Kaihotsu[3]
[1] National Institute of Technology, Matsue College, Japan; [2] Faculty of Environmental design, Kanazawa University, Japan; [3] Hiroshima University, Japan

ABSTRACT

Estimation of the land surface emissivity is crucial to evaluate the boundary conditions of atmospheric modeling data assimilation. Brightness temperatures observed by satellite passive microwave radiometer give information on emission forma raindrops and scattering by frozen particles. By applying radiative transfer model of the atmosphere, we can estimate the atmospheric hydrological process (i. e., rainfall, snowfall, water vapor, cloud water, etc.). However it is difficult to estimate microwave land surface emissivity at higher frequencies over land. Because land use, land cover and surface wetness over land are various and heterogeneous by comparing with over ocean. Therefore, we aim to estimate the microwave land surface emissivity over East Asia by using observed data and numerical models.

Firstly, we investigate the characteristics of land surface emissivity derived from SSM/I, AMSR-E and AMSR2 over Asia and the relationship between land surface emissivity and land hydrological variables based on satellite data sets and numerical models. Secondary, we estimate the land surface emissivity by applying the Community Microwave Emission Model (CMEM) and Community Radiative Transfer Model (CRTM).

Keywords: Microwave land surface emissivity, CRTM, CMEM, Japan, Mongolia

INTRODUCTION

Microwave land surface emissivity at higher frequencies is crucial for cloud data assimilation for heavy rainfall. Cloud data assimilation has great potential to improve the prediction of heavy rainfall area because it can directly obtain information on locations of rain systems. Clouds can be observed globally by satellite-based microwave remote sensing. Therefore, satellite-based microwave remote sensing has Retrievals of land surface emissivity (LES) are challenging due to the high variability of emissivity and its sensitivity to land surface hydrological parameters [1], [2], [3]. Passive microwave remote sensing such as AMSR-E and AMSR2 has the advantages of considerably high revisit time and having multiple channels that are sensitive to different atmospheric variables and surface properties [4], [5], [6].

The objectives of our study are to investigate the temporal and spatial variability of LSE over East Asia, to reveal the relationship between LES at low frequency (6.9GHz and 10.7GHz) and high frequency (36.5GHz and 89.0GHz) by exploring the AMSR-E Monthly Global Microwave LSE dataset obtained from National Snow and Ice Data Center (NSIDC) and to estimate the LES at Mongolia observation sites from 2002 to 2008 by applying the Community Microwave Emission Model (CMEM) and Community Radiative Transfer Model (CRTM).

CMEM is developed by ECMWF for low frequency passive microwave brightness temperatures from 1 GHz to 20 GHz of the surface.

To estimate LES at higher frequencies by applying CMEM, we should clarify the relationship of LES between low and high frequency using NSIDC LES data set. On the other hand, CRTM with the land microwave emissivity component is used in a wide frequency range from 1 GHz to 100 GHz. Microwave LES at higher frequency is directly estimated by applying CRTM.

CARACTERISCS OF LAND USE AND LAND SURFACE EMISSIVITY OVER EAST ASIA

Microwave land surface emissivity strongly depends on the land surface condition (i. e., land use, land cover, vegetation type, surface wetness, surface roughness, etc.). Therefore, we investigate the relationship between land surface emissivity and land use by using satellite observation date.

All of the seven channels with vertical and horizontal polarizations of AMSR-E/Aqua Global Monthly LSE at 0.25° latitude/longitude for the study period from July 2002 to June 2008 were obtained from data providing service at NSIDC.

Our target areas are Mongolian Plateau and Japan.

Mongolian Plateau

Firstly, Mongolian Plateau area is shown in Fig. 1a. These figures also show the classification of land cover by using the dataset of USGS (Unite States Geological Survey) Global Land Cover Characterization Version 2.0. Figure 1b shows the relative frequency of land cover in the histogram. Glassland, shurabland and Barren or Sparesly vegetated are mainly covered with our target area. The characteristics of land cover in our area is less vegetated condition.

Fig. 2a presents the comparison between land surface emissivity at low frequencies (6.9GHz and 10.7GHz) and other high frequencies in July 2002 at grassland area. It represents the relationship between land surface emissivity and land hydrological variables (land type, land use, vegetation and soil moisture) in summer. The LSE at 6.9GHz with horizontal polarization is related with at higher frequencies. However, variation is large in the relationship between LSE at 6.9GHz and at 89.0GHz with horizontal polarization.

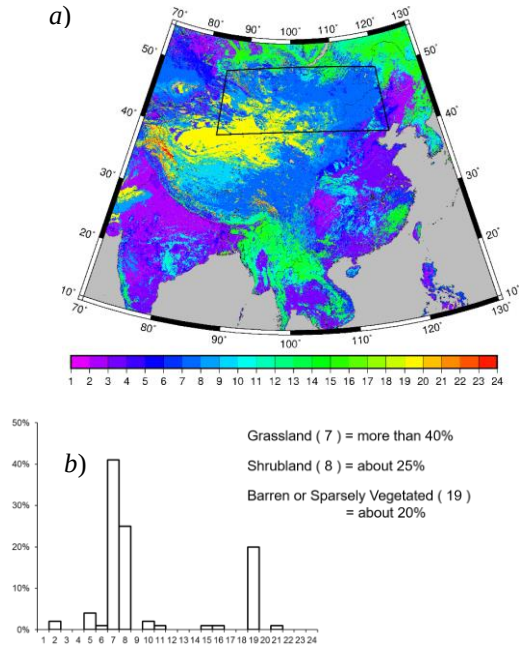

Fig. 1 *a*) Land cover classes and *b*) the relative frequency of land cover over Mongolian Plateau area.

Relationship between LES at low frequency and high frequency

Fig. 2b shows the comparison between LSE at low and high frequencies at bare soil area. By comparing Fig. 2a, we found that liner relationship between low-frequency LES and high frequency LES is clear. These figures implies that microwave LSE at high frequency is estimated by using microwave low-frequency LES in summer.

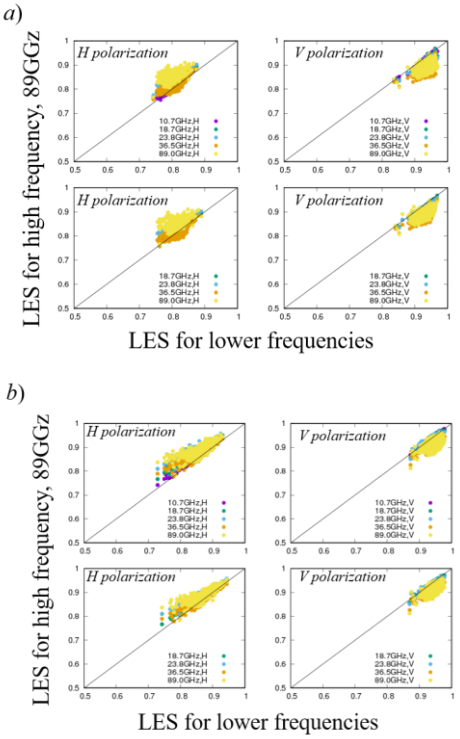

Fig. 2 Relationship between low-frequencies and high frequency LES over *a*) glass-land area and *b*) bare soil area shown in Fig. 1a.

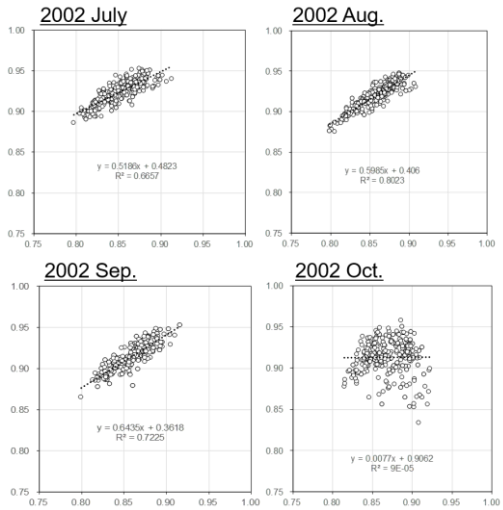

Fig. 3a Seasonal change of relationship between low-frequencies and high frequency LES from July 2002 to October 2002 at bare soil area shown in Fig. 1a.

Relationship in barren or sparsely vegetated area

Fig.3 shows the seasonal change of its relationship over barren or sparsely vegetated area. It is found that correlation coefficient in summer (from July to September) is higher compared with one in winter.

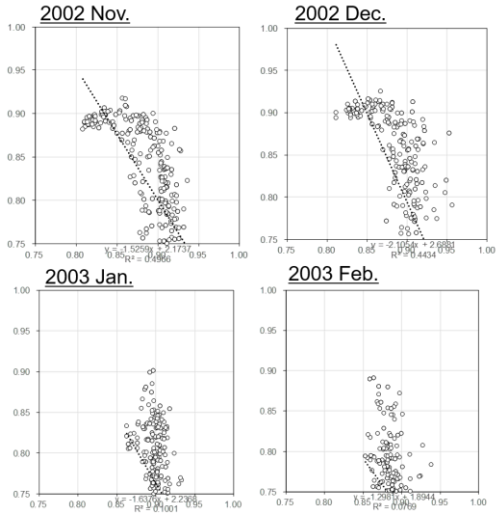

Fig. 3b Seasonal change of relationship between low-frequencies and high frequency LES from November 2002 to February 2003 at bare soil area shown in Fig. 1a.

Japan

Secondary, Fig. 4 shows the relative frequency of land cover over Japan in the histogram by using the dataset of USGS Global Land Cover Characterization Version 2.0. As compared with Mongolian Plateau, Japan area is covered with forest more than 90% as show in Fig. 4.

We investigate the relationship between low frequency LES and high frequency LES. However, we could not found its relationship. It is because that our target area is cover with dens vegetated and various land cover.

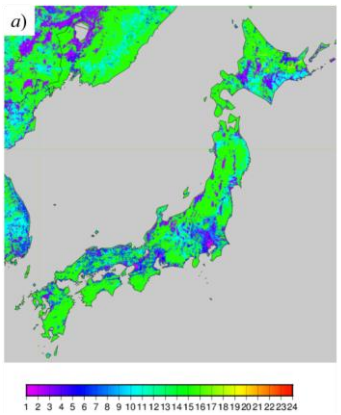

Fig. 4a Land cover classes over Japan.

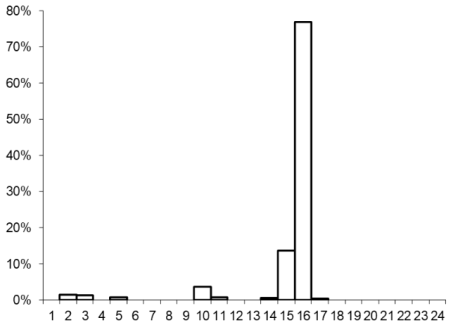

Fig. 4b Relative frequency of land cover classes over Japan.

ESTIMATION OF LAND SURFACE EMISSIVITY

The Community Microwave Emission Model, CMEM comprises the physics and parameterizations used in the Land Surface Microwave Emission Model (LSMEM) [7] and the L-Band Microwave Emission of the Biosphere (L-MEB) [8], [9].

Community Microwave Emission Model (CMEM)

CMEM was developed by the ECMWF for numerical weather prediction applications and is used to simulate passive microwave brightness temperatures of the surface at low frequencies (from 1 GHz to 20 GHz) [10], [11], [12]. For polarization (p), the brightness temperatures over snow-free areas at the top of the atmosphere (TOA) $T_{Btoa,p}$, which result from the contributions of three dielectric layers (soil, vegetation, and atmosphere), can be expressed as follows:

$$T_{Btoa,p} = T_{Bau,p} + e^{-\tau_{atm,p}} \cdot T_{Btov,p} \quad (1)$$

$$T_{Btov,p} = T_{Bsoil,p} \cdot e^{-\tau_{veg,p}} + T_{Bveg,p}(1 + r_{r,p} \cdot e^{-\tau_{veg,p}}) + T_{Bad,p} \cdot r_{r,p} \cdot e^{-2\tau_{veg,p}} \quad (2)$$

where $T_{Btov,p}$ is the top-of-vegetation brightness temperature when the vegetation is represented as a single-scattering layer above a rough surface; $\tau_{atm,p}$ is the atmospheric optical depth; $T_{Bau,p}$ and $T_{Bad,p}$ are the upward and downward atmospheric emissions, respectively; and $T_{Bsoil,p}$ and $T_{Bveg,p}$ are the soil and vegetation layer contributions, respectively. Here, $r_{r,p}$ is the soil reflectivity of a rough surface (one minus the emissivity $e_{r,p}$), and $\tau_{veg,p}$ is the vegetation optical depth along the viewing path.

Simulation Results

We address long-term land hydrological dataset measured at Mongolia observation sites. By applying to CMEM, land surface emissivity at 6.9GHz with horizontal and vertical polarization are estimated at Mongolia site.

Fig. 5a and 5b present the comparison between simulation results at Mongolia site by using CMEM and AMSR-E Monthly Global LSE. Fig. 4a shows the simulated microwave LSE at 6.9GHz with horizontal polarization is overestimated and its temporal variability is very large.

On the other hand, Fig. 5b shows the simulation result with vertical polarization is good agreement with AMSR-E Monthly LSE at Mongolia observation site.

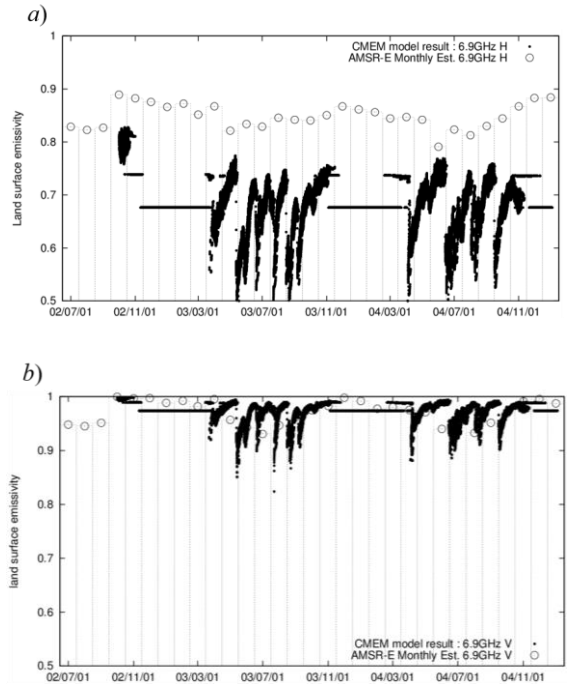

Fig 5. Comparison between the observed microwave LES and simulation results with *a*) Horizontal polarization and *b*) Vertical polarization.

CONCLUTION

In this study, we investigate the temporal and spatial variability of LSE over Asia and the relationship between LES at low frequency (6.9GHz and 10.7GHz) and high frequency (36.5GHz and 89.0GHz) and try to estimate microwave land surface emissivity from July 2002 to January 2005 at Mongolia observation sites.

Firstly, Microwave LES at high frequencies is related to LES at low frequencies in summer. It implies effect of land surface hydrological variables to LES. Therefore, we try to identify the effect of snow, vegetation type and soil moisture by using Land use and MODIS dataset. Secondly, Microwave LES at 6.9GHz with horizontal and vertical polarization is simulated at Mongolia observation sites. Simulation results shows the estimated LSE is overestimated and its variability is large by comparing the observed data.

We should reveal the effect of snow and vegetation type to the relationship between LES at low and high frequencies and calibrate CMEM model parameters to represent the temporal and spatial variability of LSE obtained from AMSR-E and AMSR2.

ABSTRACT

The lake's catchment area is one of the objects of land use conversion as a space for community needs. The boundary of the Lake Rawa Besar has been widely used by the surrounding community to carry out activities. Human activity and land use around lake borders can affect water quality. This study aims to look at the pattern of spatial distribution of Lake Rawa Besar water quality and its relationship with land use in the border. Water quality was tested based on the instant surface water sampling method in 30 samples evenly distributed in the water body and laboratory testing based on 6 water quality parameters such as turbidity, BOD, total phosphate, total solid, pH, and nitrate. Water quality is measured based on the water quality index level of WQI (Water Quality Index) and interpolated using the IDW method. Large-scale land use is used from digitizing large resolution images and potential sources of pollutants obtained from field observations. The results showed that the water quality in water bodies was almost evenly distributed with mild polluted criteria. Land use in the form of domestic activities affecting the quality of water in the Lake Rawa Besar is characterized by high turbidity and BOD values, while the total phosphate, total solid, nitrate, and pH value is low. The high correlation between turbidity and BOD which is impacted from land use concluded that the poor quality of the lake's water was caused more by organic waste.

Keywords: Water Quality Index, Inverse Distance Weighted, interpolation, land use, pollutant source

1. INTRODUCTION

The lake's catchment area is also one of the objects of land use conversion as a space for community needs. Various activities that make people live around the lake's catchment area to make use of land [1] Water bodies located in urban areas serve as reservoirs for surface runoff and are sensitive to activities around them, especially settlement activities [2].

Dense population settlements are a sign of the many human activities in the area around Lake Rawa Besar. Lake Rawa Besar also has varied land uses, namely settlements, trade, gardens, neighborhood roads, and public facilities. The effect of land use resulted in an increase in the amount of pollutants and domestic wastewater which were disposed of in Lake Rawa Besar [3].

Domestic wastes are at risk of disrupting the quality of water in a body of water and affecting several types of parameters, namely BOD, nitrate, and total phosphate [4] – [5]. Water runoff containing waste such as industrial products and waste trees and chemicals will affect the parameters of water quality such as turbidity, total solid, and pH [6] – [8].

For this reason, this study is important. The reason for the importance of the study is that the quality of water in a water body requires serious attention and management, especially from surrounding communities and governments that have authority [9]. In addition, water sources and water buildings, including those there, must be protected, secured, maintained and preserved [10].

2. DATA AND METHODS

2.1. Study Area

This research was conducted in Lake Rawa Besar and its surrounding area. Lake Rawa Besar is located in Pancoran Mas District, Depok City, West Java Province. The Lake is located between two villages, namely Depok and Depok Jaya Villages. The absolute location of the Lake Rawa Besar is 6º23'27" - 6º23'53"S and 106º48'54" - 106º49'2"W. Lake Rawa Besar has an area of about 12.92 hectares.

2.2. Water Quality

Water samples tested based on water quality parameters have 30 locations spread in Lake Rawa Besar. The location of the water sample has its own characteristics. The distribution map of the location of the water sample and the imagery of the area is shown in Fig. 1.

Water quality data used are turbidity, BOD, total phosphate, total solid, pH, and nitrate parameters. Water quality data with the 6 parameters are produced from the results of testing 30 water samples in the

AAS Cilodong laboratory. The data will then be compared with the quality standards that have been previously set as a comparison between the water quality standard value.

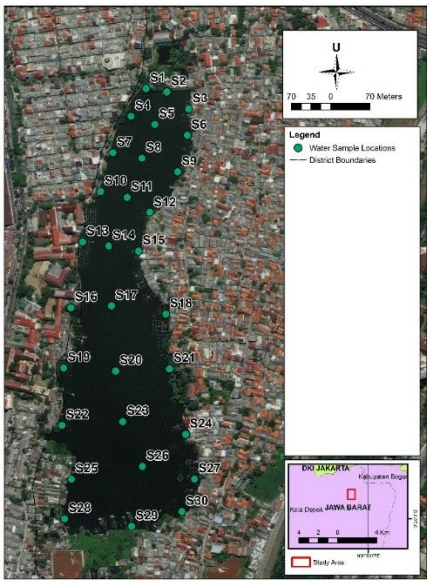

Fig. 1 Water Samples in study area

Water quality data processing is the first step that needs to be done in this study, because spatial pattern data is obtained from the processing of water sample data that has been tested. The water quality index is first calculated using WQI. Each sample point location was calculated to determine the water quality index amount at each point. The formula used to calculate WQI is in Eq. (1) [11]. The standard value used in the WQI calculation are shown in Table 1.

$$WQI = \frac{\Sigma\left[\frac{C_i}{Pl_i}\right]}{n} \quad (1)$$

WQI = Water Quality Index
C_i = Concentration of i variable
Pl_i = Standard value allowed for i variable
n = number of variable

Table 1 Standard value of water quality

Parameters	Standard Values
Turbidity	25 NTU
BOD	2 mg/L
Total Phosphate	0.2 mg/L
Total Solid	1050 mg/L
pH	6,5 – 8,5
Nitrate	10 mg/L

Water quality data is prepared to be interpolated. The interpolation that will be used is Inverse Distance Weighted (IDW) interpolation. Interpolation methods can be used to estimate objectively the spatial distribution of data [12]. Interpolation was carried out to determine the spatial distribution of WQI calculation results in the waters of Lake Rawa Besar. Data to be generated from interpolation is the distribution of WQI for each parameter and total distribution of WQI.

After that, categorization of the water quality level was carried out to see the spatial distribution of the water quality index of each parameter and the total water quality index in the Lake Rawa Besar area. The level of water quality used is the water quality classification criteria [13]. The criteria classification for WQI can be seen in Table 2.

Table 2 Water Quality Index Criteria

WQI value	Criteria
WQI ≤ 0,30	Excellent
0,31 ≤ WQI ≤ 0,89	Clean
0,90 ≤ WQI ≤ 2,49	Mild Polluted
2,50 ≤ WQI ≤ 3,99	Moderately Polluted
4,00 ≤ WQI ≤ 5,99	Heavily Polluted
WQI ≥ 6,00	Dirty

2.3. Land use

Secondary data used in this study is Digital Globe imagery data. The imagery is then digitized to obtain several land use variables. The variables used in digitizing land use are buildings, gardens, and environmental roads. Land use is digitized at a scale of 1:5000. Pollutant sources within land use also identified by field observing the land study area.

3. RESULTS AND DISCUSSION

3.1. Turbidity

The results of WQI calculation of water turbidity parameters indicate an index based on a review of water quality turbidity standards. The WQI level based on turbidity parameters produces 5 criterias for water quality level, which are clean, mildly polluted, moderately polluted, and heavily polluted. Two samples counted as water with clean water quality, 3 samples were mildly polluted water, 9 samples were moderately polluted water, 12 samples were heavily polluted water, and there were 3 samples which were dirty water based on turbidity parameters.

Spatially, the turbidity in Lake Rawa Besar has a high value in areas close to the land. Turbidity with high numbers also exists in the northern part of the

lake. The more center part of the lake showing the smaller turbidity value. This is shown in samples 17 and 20 in the middle of the lake. In the north, water samples show small values in samples 4, 8, and 9. The more toward the edge of the lake, the turbidity value increases. Turbidity WQI spatial pattern in Lake Rawa Besar is shown in Fig. 2.

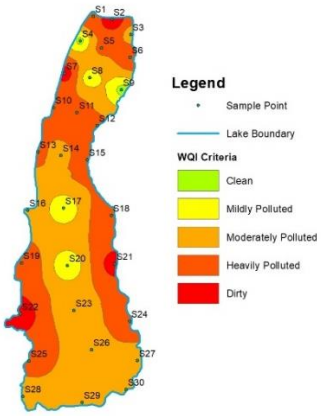

Fig. 2 Turbidity WQI Spatial Pattern within Lake Rawa Besar

3.2. BOD

The BOD in Lake Rawa Besar shows a number that is quite varied. Samples 1 to 30 have a variety of values. Spatially, the BOD in Lake Rawa Besar has higher value at several sample points, such as in the north of the lake and in the middle of the lake near the edge of the lake. The BOD in Lake Rawa Besar is quite uniform with mildly polluted criteria scattered throughout the lake. BOD with a high value is on the edge of the lake with a presence that is not too dominant towards the overall value of BOD. BOD WQI spatial pattern in Lake Rawa Besar is shown in Fig. 3.

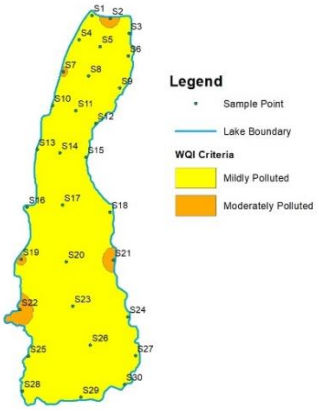

Fig. 3 BOD WQI spatial pattern within Lake Rawa Besar

3.3. Total Phosphate

The total phosphate present in Lake Rawa Besar shows almost uniform values. Spatially, the total phosphate present in Lake Rawa Besar has a higher value at several sample points, such as in the western part of the lake, precisely in the middle and at the southern edge of the lake. Total phosphate in Lake Rawa Besar is quite uniform with excellent criteria spread throughout the lake. Total phosphate with clean criteria is at the edge of the lake with a less dominant presence in the total value of total phosphate. Total phosphate WQI spatial pattern in Lake Rawa Besar is shown in Fig. 4.

Fig. 4 Total Phosphate WQI spatial pattern within Lake Rawa Besar

3.4. Total Solid

The total solids value shows that 30 water samples have total solids that do not exceed the quality standard which is valued 1050 mg / L. Spatially, the total solids present in Lake Rawa Besar have uniform WQI values. There is only one water quality criteria based on the total solids parameter, which is water that is considered excellent.

Fig. 5 Total Solid WQI spatial pattern within Lake Rawa Besar

3.5. pH

WQI level based on pH parameters produces 1 type of water quality criteria, which is lightly polluted. All water samples have a pH value that is included in the criteria for mild contamination. Spatially, the existing pH in Lake Rawa Besar has a uniform WQI value. There is only one water quality criterion based on pH parameters, namely water which is critically polluted.

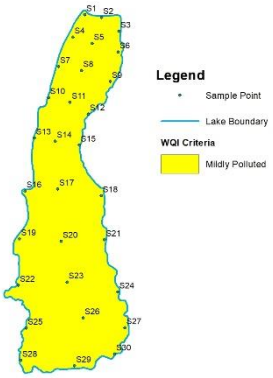

Fig. 6 pH WQI spatial pattern within Lake Rawa Besar

3.6. Nitrate

The nitrate value also shows that 30 water samples have nitrates that do not exceed the water quality standard which is worth 10 mg / L. Spatially, nitrates in Lake Rawa Besar have uniform WQI values. There is only one water quality criterion based on the nitrate parameter, that is, water that is critically clean.

Fig. 7 Nitrate WQI spatial pattern within Lake Rawa Besar

3.7. Landuse

The lake's catchment area has different uses around it, such as settlement, market, public buildings, and vegetation cover. The details of the building classification such as permanent and semi-permanent house, permanent and semi-permanent commercial building, house with garden cover, and also public building differentiate by the difference of the uses. The figure can be seen on Fig. 8

The west side of Lake Rawa Besar also has a permanent house built in Depok City Housing. In addition, there is also a school complex consisting of several elementary, middle, high school, vocational schools, and foundations that have several levels of schools. On the same highway there are also many buildings that are used as trade.

Utilization in the form of a garden house is in the eastern part of Lake Rawa Besar. In the garden house, this house is in a garden that grows wild trees and there is no path to the house. Around the garden house there is a garbage dump and a chicken coop.

In addition to land use in the form of area, there are also places for surrounding community activities such as poultry cages, fish cages, iron workshops, wood sawmills, tofu factories, garbage dumps, and food stalls that have the potential to become pollutant sources for Lake Rawa Besar. Some chicken coops are in slums in the west of Lake Rawa Besar, but there are also several locations in the north and east of Lake Rawa Besar.

The type of land use in the north tends to be dominated by permanent houses. The northern part of Lake Rawa Besar on the edge of Lake Rawa Besar also has a lot of semi-permanent commercial building. Public buildings in the form of schools are mostly located in the west of Lake Rawa Besar. In the southwest there are semi-permanent houses because of the existence of slum settlement located on the banks of Lake Rawa Besar. There are uses of many garden lands in the edge around the lake. Permanent commercial buildings on the edge of highways are found in the western part of public buildings. There are several garden houses around slums and gardens.

There are some pollutant sources such as chicken coops in slums behind the school area and in the north and east of Lake Rawa Besar. Fish cages located on the edge of the Lake Rawa Besar are spread almost evenly in water bodies near permanent settlements in the eastern part of the lake and slums.

The boundary of the Lake Rawa Besar also has an inlet flow in the form of sewers and culverts flowing into the lake body. The use of land and sources of pollutants that exist in the boundary of the Lake Rawa Besar has the potential to affect the lake and flow through the inlet to the water body.

3.8. The Effect of Landuse to The Water Quality

This study found that turbidity and BOD parameters is more variative scattered in the water body than total phosphate, total solid, pH, and nitrate. These may indicate that the water turbidity and BOD level in the waters of Lake Rawa Besar can be affected by the land use surrounding the lake. The lake's catchment area mostly in the form of built-up land, such as settlements, commercial areas, and school zones are heavily filled with pollution source caused by human activities. The existence of settlements producing household waste can be a major cause of high BOD values so that water becomes turbid [14].

The dominance of permanent home land use and environmental roads does not affect water quality, but the use of trade land in the north with the type of trade land use and source of pollutant landfills affects several water quality parameters, such as turbidity entering the dirty criteria and BOD entering the moderately polluted criteria. Uneven turbidity in Lake Rawa Besar has varying characteristics of land use, such as extensive garden areas in the south, as well as several landfills in parts of the slum area around semi-permanent houses area. Turbidity with dirty levels is also found in the north of Lake Rawa Besar with the type of land use dominated by gardens and the use of semi-permanent commercials, but there are several landfill locations on the edge of Lake

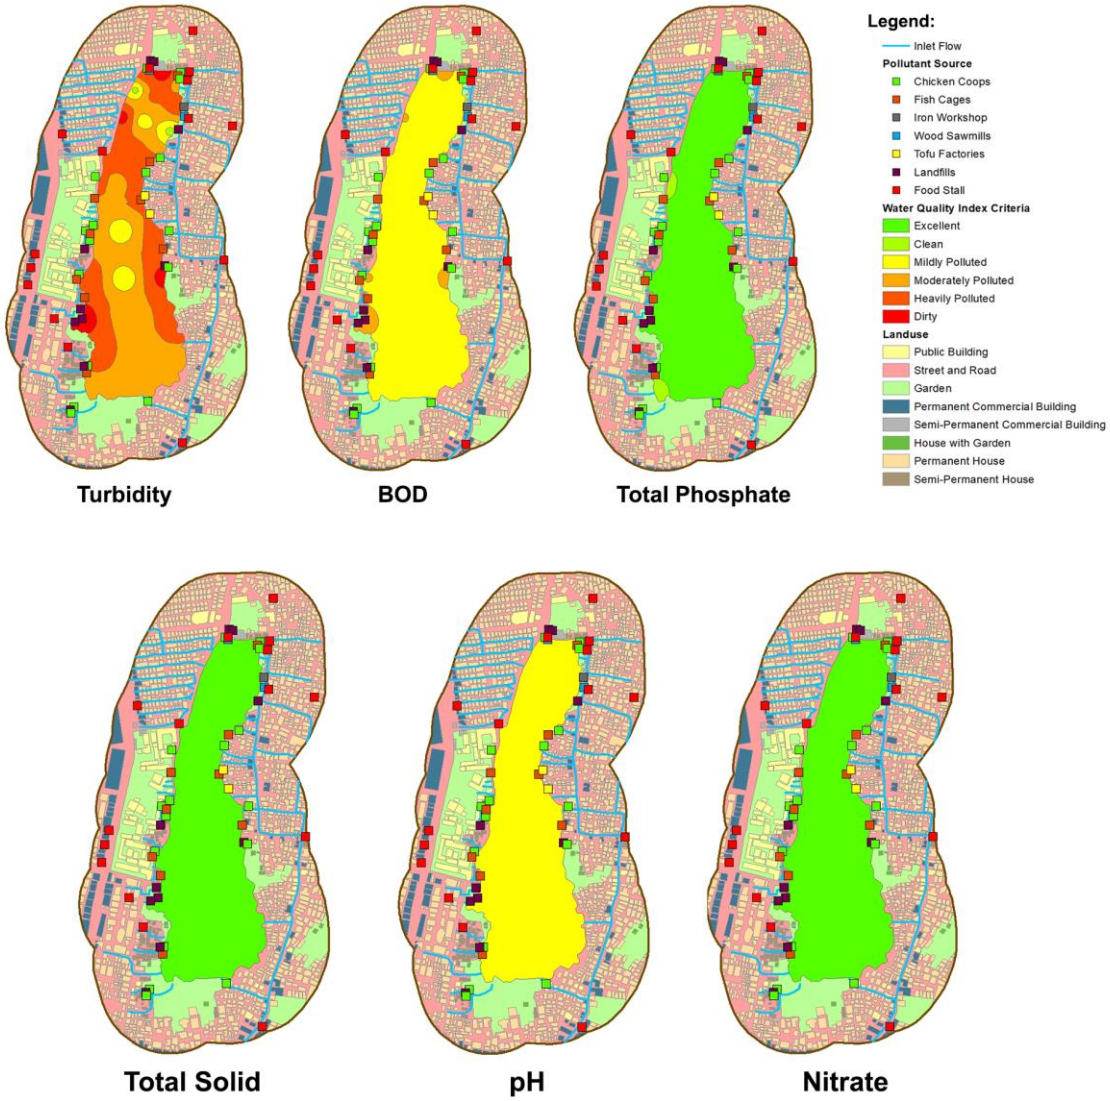

Fig. 8 WQI parameter values with landuse around Lake Rawa Besar

Rawa Besar. Some locations for food stalls and chicken coops do not affect the total phosphate value, but some locations of chicken coops and landfills are related to the location of BOD values that are included in the medium polluted criteria.

The total phosphate parameters are related to agricultural and plantation activities that produce chemical waste and runoff of large and small materials. The total phosphate value is only slightly higher in the western part of the back of the school area and gardens near the southern part of the housing complex. It is possible that more disposal of chemicals and wastes is found in the vicinity of slums, especially there are also poultry cages in that location.

4. CONCLUSIONS

The pattern of spatial distribution of Lake Rawa Besar water quality based on the total value of the WQI produces a relatively clean and increasingly dirty central part of the lake towards the edge of the lake. The spatial distribution of water quality turbidity and BOD parameters has a similar pattern, which is high on the edge and lower in the middle. The water quality of the total phosphate parameters has an almost uniform pattern, namely the excellent criteria that is evenly distributed in the Lake Rawa Besar water body. The pattern of spatial distribution of water quality is closely related to land use and the existence of potential sources of pollutants. The high BOD and turbidity values are caused by domestic waste.

ABSTRACT

Coastal areas have been used as a settling ground for human population as they provided abundant fisheries and marine resources and possibilities for business sectors. Coastal hazards cause loss of life and the degradation of coastal environment. It defined as physical phenomena that expose a coastal area to risk of property damage. Coastal areas are frequently changing, in which natural hazards such as tsunamis is one of the sources. The management of coastal hazard currently has become an important aspect for coastal planning in order to improve the resilience of society to coastal hazards. Coastal disaster management can be done based on the risk analysis using several vulnerability and risk parameters. The current research tried to analyze the potential risk area due to tsunami hazard using the parameter of vulnerability in the coastal area of East Java Indonesia. Risk map produced from the geospatial database analysis in the concept of the geographical information system (GIS). Risk assessment combines the outputs of vulnerability assessments and the hazard, in which the topography elevation, type of building, land cover, coastal vegetation density, and the type of coastline build the vulnerability map. Historical data of some tsunami events indicates that some of the damage caused by the coastal elevation as one of the physical parameters of tsunami vulnerability, as well as social parameters. The study describes an important result related to multi-criteria processing in predicting the tsunami risk area. GIS plays as important approaches in combining the geospatial database of each parameter and displays it in geographical perspective.

Keywords: Geographical information system, hazard, tsunami, risk, vulnerability

INTRODUCTION

The development of coastal areas today is more focused on the consideration of environmental degradation. Various kinds of hazard threats to the coastal environment, such as natural disasters and other natural phenomena, are also considered in the management of coastal areas. Coastal areas are one of the areas that are susceptible to environmental damage, both caused by the pressure of human activities and the consequences of natural disasters.

Coastal hazards can be defined as physical phenomenon that exposes a coastal area to risk of property damage, loss of life and environmental degradation. In the term of coastal zone management, coastal hazard management has become an increasingly important aspect. This is important to improve the resilience of society to coastal hazards. Possible management options include the design of coastal structures, application of natural coastal green for coastal protection, various accommodation approaches as well as a managed infrastructure in the area close to the coastline. For overcoming coastal hazards, it is also important to have early warning systems and emergency management plans in order to be able to address sudden and potential disastrous hazards i.e. major flooding events, tsunami, or hurricane. Events as the 2004 Indian Ocean earthquake and tsunami, the Hurricane Katrina affecting the southern USA in 2005, the cyclone Nargis affecting Myanmar in 2008, the 2011 Tohoku, Japan earthquake and tsunami, and also the 2018 Sulawesi, Indonesia earthquake and tsunami provides clear examples of the importance of timely coastal hazard management.

The purpose of mitigation is not only to minimize the loss of property damage but also minimize the damages of environmental due to development. Disaster mitigation program also important approaches in order to avoid impacts by not taking actions, to reduce impacts by rehabilitation the affected environments or constructing long-term maintenance operations, and compensating for impacts by providing substitute environments for resources.

Through human history, developing technology has increased the range of adaptation options in the face of coastal hazards, and there has been a move from retreat and accommodation to hard protection and active seaward advance via land claim as exemplified by the Netherlands [1].

in general coastal hazards can be grouped into five main impacts, usually with several contributing

processes causing cumulative harm; (1) coastal erosion and coastline stability (including the area of river mouths, tidal inlets and cliffs) from waves, storm tide, changes in sediment budgets, river floods, coastal structures, storm water, and sea-level rise; (2) coastal flooding cause from storm tide, river floods, tsunami, and sea-level rise; (3) the level of groundwater in the coastal area due to storm tide, intense rainfall, sea-level rise, and salinization; (4) recreational activities together with hazards arising from surf zone conditions (e.g. rips, wave conditions, long-wave surges); (5) oceanic activities together with marine navigation hazards arising from wave conditions, storm tide, strong winds, long-wave surges and also tsunami.[2].

The application of Geographical Information System (GIS) for disaster research provides an important integrated contribution in order to assess the risk of the coastal area due to the natural disaster [3]. The development of satellite remote sensing technology and its applications enable the use of satellite imagery for mapping the distribution of an area damaged by a disaster. Satellite images have the advantage of being able to deliver simultaneous images of wide areas [4]-[5]-[6]. In addition, with the aid of the GIS, spatial multi criteria analysis helps prioritize the decision-making process using spatial database. Spatial multi criteria analysis is vastly different from conventional Multi Criteria Decision Making (MCDM) techniques, due to the inclusion of an explicit geographic element.

GIS mapping of tsunami vulnerability has also applied using the Shuttle Radar Topography Mission (SRTM) to obtain the topographic data of the study area [7]-[8]. Another geospatial analysis approach has applied soil type, urban form and social type system for the potential natural hazard mapping [9] and has assessed the tsunami vulnerable area by comparing building damage map with the physical topography data includes elevation, land use, and the distance from the coast [10]. Mapping of the 2011 Tohoku earthquake tsunami inundation and run-up by in-situ survey also has been published in order to develop create appropriate disaster mitigation concepts [11].

This study tried to apply several physical topography data for analyzing coastal hazard and its affected areas, especially caused by the tsunami disaster using GIS approach.

METHOD

Study Area

The analysis was applied in three different case study areas around the coastal area of Indonesia in order to know the different result of applying physical topographic dataset. The area includes the coastal area of Java Island and divided into the western part of Java which is represented by Banten Regency areas, the eastern part of Java Island which represent by Banyuwangi Regency, and also Malang regency area which represents the area that directly faces to the Indian Ocean. The study area as describe on Fig. 1.

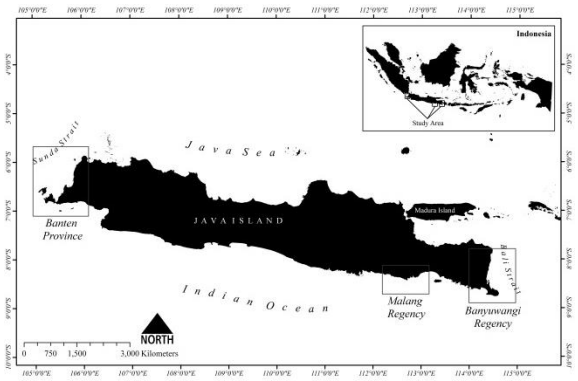

Fig. 1 Study area

Dataset

Physical data set for assessing the affected area of tsunami disaster in all coastal areas of case study was collected. This dataset includes topography elevation, slope, building area, coastal proximity and coastal type, and also population density as well. For providing the physical topographic parameters, the dataset of The ASTER Global Digital Elevation Model (ASTER GDEM) version 2 was collected from *https://gdex.cr.usgs.gov/gdex/*. This data are available from the Land Processes Distributed Active Archive Center (LP DAAC). Moreover, The NASA Shuttle Radar Topographic Mission (SRTM) also collected for preparing topographic elevation dataset. SRTM has provided digital elevation data (DEMs) for over 80% of the globe and distributed by USGS and is available for download from the National Map Seamless Data Distribution System, or the USGS ftp site. The SRTM data is available as 3 arc second and downloaded from *http://srtm.csi.cgiar.org/srtmdata/*.

In addition to provide land use map that describe also the building areas, Sentinel 2 satellite image was applied. Sentinel-2 is a European wide-swath, high-resolution, and multi-spectral imaging mission. The full mission specification of the twin satellites flying in the same orbit but phased at 180°, is designed to give a high revisit frequency of 5 days at the Equator. Sentinel-2 carries an optical instrument payload that samples 13 spectral bands: four bands at 10 m, six bands at 20 m and three bands at 60 m spatial resolution. The orbital swath width is 290 km [12]. This data was collected from *https://scihub.copernicus.eu/dhus/#/home.*

The type of coastal, distance from coastline to hinterland (coastal proximity), and other land use

feature were created from vector data of base map. This data was collected from Indonesia Geospatial Information Agency. Dataset that used in the analysis as described in Table 1, Table 2, and Table 3.

Table 1 Specification of DEM data

	Aster GDEM	SRTM
Data source	ASTER	Space shuttle radar
Generation and distribution	METI/NASA	NASA/USGS
Release year	2009 ~	2003 ~
Data acquisition period	2000~ongoing	11 days (in 2000)

Data Analysis

As one of the potential natural disasters that affect to the dynamic of coastal area, the affected area due to tsunami could be assess through the analysis of risk and vulnerability. In order to analyse this assessment, all parameters will be analyzed using GIS. GIS helps in the integration of all dataset geographically.

DEM dataset collected will be calculated for producing topographic elevation data and slope. This elevation and slope data will then be analyzed spatially based on the risk standard and vulnerability of these two parameters to produce a map of coastal area vulnerability to tsunami hazards. DEM data will be visualized using surface analysis in GIS as well as the slope was created from the DEM data. DEM data will be visualized using surface analysis in GIS as well as the slope was created from this DEM data.

The distance from coastline to the hinterland (coastal proximity) and the radius zone from river was calculated and created using vector base map of the study area and analyzed through multi-ring buffer of proximity analysis in GIS. In order to set the radius number of coastal proximity for assessing the risk area due to tsunami, Eq. (1) was applied.

$$log X_{max} = log 1400 + {}^{4}/_{3}\, log\left({}^{Y_0}/_{10}\right) \quad (1)$$

In which, X_{max} is represent the maximum reach of the tsunami over land, and Y_0 is the height of the tsunami at the coast. For applying this algorithm, a set of tsunami historical data which describe the information of maximum run-up in the area of study was collected. The class number of this coastal proximity was different for three research areas. Type of coastline was created also using vector base map of the study area by digitizing polyline data of the coastline and categorized it based on the coastal morphology type.

For preparing the land use data and build area of the study area, Sentinel-2 satellite image was analyzed using image classification process. The satellite image processing starts with the computation of TOA (Top of Atmosphere) Reflectance. The numeric digital counts (CN) of each pixel image (*i*,*j*) and each spectral band (*k*) are converted in TOA reflectance (ρ). This conversion takes into account the equivalent extra-terrestrial solar spectrum (*Es*), the incoming solar direction defined by its zenith angle (θs) for each pixel of the image and the absolute calibration (*Ak*) of the

Multispectral Instrument (MSI). As explained in Sentinel-2 technical guides [13], The TOA conversion equation as described in Eq. (2).

$$\boldsymbol{\rho_k(i,j) = \frac{\pi \times CN_{k.NTDI}(i,j)}{A_{k.NTDI} \times E_S \times d(t) \times \cos(\theta_s(i,j))}} \quad (2)$$

where:
$CN_{k.NTDI}$ is the equalized numeric digital count of the pixel (*i,j*) with NTDI, the number of Sentinel-2 TDI lines. E_s is the equivalent extra-terrestrial solar spectrum and depends on the spectral response of the Sentinel-2 bands. The component *d(t)* is the correction for the sun-Earth distance variation (as described in Eq. (3)). It utilises the inverse square law of irradiance, under which, the intensity (or irradiance) of light radiating from a point source is inversely proportional to the square of the distance from the source [13].

$$\boldsymbol{d(t) = \frac{1}{(1 - 0.01673 \times \cos(0.0172 \times (t-2)))^2}} \quad (3)$$

Where :
t is the Julian Day corresponding to the acquisition date. 0.01673 is the Earth orbit eccentricity. 0.0172 is the Earth angular velocity (radians/day). The parameters *Ak* and *Es* are provided by the GIPP and are also included in the ancillary data of the Level-1 products. The sun zenith angles are determined at this level too. A sun angle grid is computed by regularly down-sampling the target geometry (Level-1C tile). The cosine of the zenith angle *θs* is defined at each point of the grid using the ground coordinates and the datation of the corresponding pixel acquisition.

Reflectance value, often between 0 and 1, is converted into integer values, in order to preserve the dynamic range of the data by applying a fixed coefficient (1000 by default). This reflectance value was used as standard value in image classification process in which the supervised classification method was applied using several training area.

All geospatial databases will be analyzed through a spatial overlay process, where all parameters were in the form of a raster data base and processed based on the standard value of each parameter, as illustrated in Table 4 and Table 5. Analysis carried out through GIS with a pixel-based weighted overlay process. The weights of the parameter were constructing using pair-wise comparison matrix of Analytical Hierarchy Process (AHP) method.

Table 1 The physical vulnerability value range for elevation, slope, and landuse

Vulnerability class	Elevation (m)[1]	Slope (%)[2]	Landuse[3]
High	<5	0-2	Urban
Slightly high	5-10	2-6	Agriculture
Moderate	10-15	6-13	Bare soil
Slightly low	15-20	13-20	Water
Low	>20	>20	Forest

Low	>1032	>500	Neutral

[4] Based on Eq. 1 calculations and it will be different result for different study area
[5] [7]

RESULT AND DISCUSSION

This study was one of the approaches in the integrated coastal hazard assessment, in which the analysis for describing the affected area caused by tsunami wave was studied. Analysis of all disaster risk parameters in this study obtained thematic maps of each parameter. This map illustrates the potential areas affected by the tsunami disaster. To get a conclusion of the risk area based on a combination of all parameters, a spatial overlay process for all parameters was carried out, with the multiplication concept of each pixel of parameter with its weight. The weight of each parameter was obtained from expert judgment and calculated based on the AHP approach. The conclusion of this calculation is the form of pair-wise comparison matrix with the required consistency ratio of less than 10% (2.9%), as explained in Fig. 2. The result of AHP calculation through pair-wise comparison matrix described that the elevation was parameters with the highest weight that affect the creating of risk maps. In contrast, the parameter of river distance was the lowest. In the future analysis, the different type of landcover would be important to be separated. The area with a high density of vegetation would be included in the low class of tsunami risk compare with the bare land.

In the application of parameter's weight for creating risk area map, a research on tsunami vulnerability in Alexandria was applied all parameter in equal weight due to the limitation of knowledge regarding to the study area [14]. The use of pair-wise comparison matrix in weight calculation also applied in the tsunami vulnerability mapping along coastal area of Miyagi Prefecture, Japan and. illustrated a similar pattern of tsunami vulnerability

area to the real tsunami inundation area during the 2011 Tōhoku's tsunami [15].

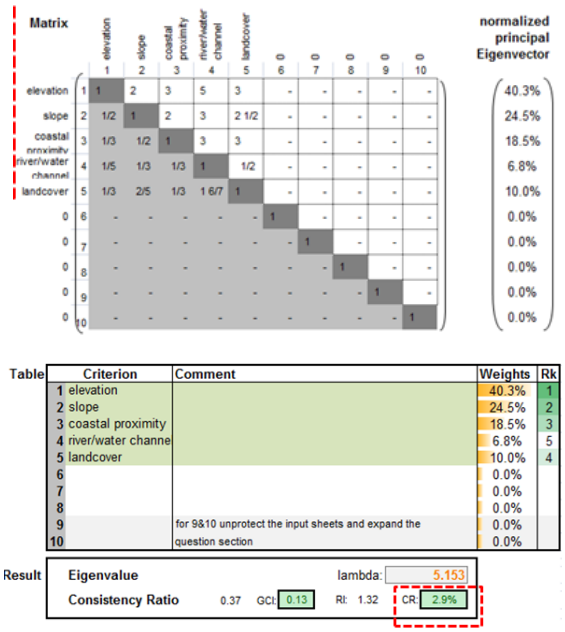

Fig. 2 Pair-wise comparison matrix and normalized principal eigenvector

The result of the analysis as describe on Fig. 3, Fig. 4, and Fig. 5. The map shows that in general the high risk areas were mostly found in the coastal area with the sloping coast type. Elevation and slope play an important role in determining the stability of the terrain in the coastal [16]. The research of tsunami vulnerability along coastal area of Bali, Indonesia described that the distribution of vulnerability is not uniform and physically it is highly influenced by the distance from coastline to the hinterland, topography elevation, and also slope [17]. The most risk area due to tsunami disaster in depends on the direction of tsunami source or the epicentre of the earthquake.

The results of this study illustrate that areas with low vegetation density, high distribution of build area, flat areas, and areas close to large rivers will have greater disaster risk. The existence of rivers in the coastal area will enable it to act as the successor to the tsunami wave that comes and takes it far towards the land until it reaches a certain elevation.

The outputs of the tsunami hazard analysis are very much dependent on data availability and the application of methods. The approaches range from simple empirical methods to sophisticated numerical simulations. Empirical methods use simplified formulas to derive tsunami hazard maps. In general, information on the elevation and the distances from coastline are applied in combination with empirical formulas to estimate the inundated areas on coastal areas [18].

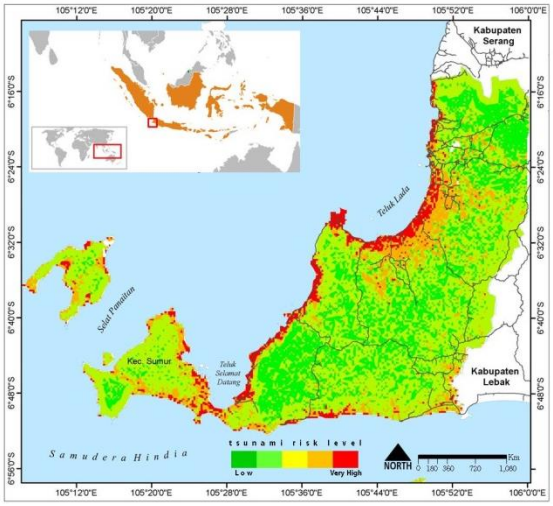

Fig. 3 Tsunami risk area in the coastal area of Banten, Indonesia

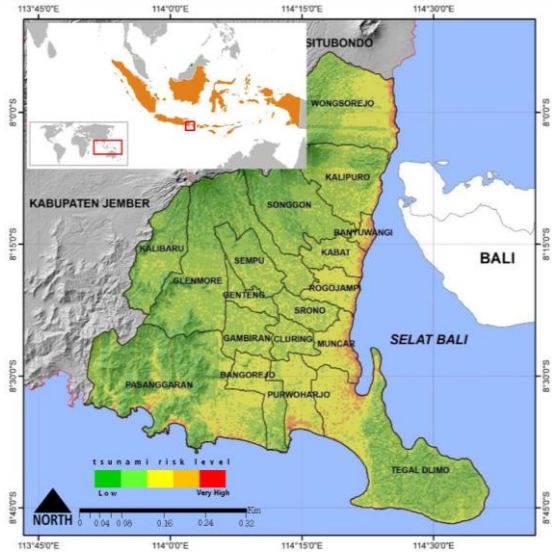

Fig. 5 Tsunami risk area in the coastal area of Banyuwangi, Indonesia

CONCLUSIONS

Risk and vulnerability assessment is one of the important steps in contributing the information regarding to the coastal hazard analysis. The concept and methods have been applied to compare the importance of using risk parameters by testing them in three different coastal regions. From the analyses key parameters are derived and integrated for assessing the risk and vulnerability map. The result will be act an important role for effective early warning system. In the future work, the social and ecological parameter will be an important parameter for analysis.

ABSTRACT

This paper presents the parametric investigation of the influence of railings on the wheel load distribution in simply-supported, one-span, three- and four-lane straight and skewed reinforced concrete slab bridges using the finite element method. A total of 96 bridge cases were modeled using finite-element analysis (FEA) and bridge parameters such as span length, slab width, and skew angle are varied within practical ranges. Typical railings built integrally with the bridge were placed on both edges of the deck slabs. AASHTO HS20 truck loadings were positioned transversely and longitudinally to produce maximum longitudinal live load bending moments in the slabs. The FEA wheel load distribution and bending moments were compared with reference straight bridges without railings as well as to the AASHTO Standard Specifications for Highway Bridges and the AASHTO LRFD Bridge Design Specifications. AASHTO overestimates FEA moments for almost all bridge cases and this overestimation increases with the increase in the skew angle, and it is more significant in the presence of two railings. Also, it was found that the reduction in slab moment due to skewness and railings is cumulative. The presence of railings can be considered to be a possible method for strengthening and rehabilitating straight and skewed concrete slab bridges.

Keywords: Concrete slab bridges, Multi-lane, Skew angle, Railings or parapets, Finite-element analysis, AASHTO procedures, Load-carrying capacity.

INTRODUCTION

A significant number of highway bridges are short-span reinforced concrete slabs that are owned and maintained by local and state governments. The main advantage of concrete slab bridges is the ease of construction and the ability to field adjustment of the roadway profile during construction.

Skewed bridges are often encountered in highway design when the geometry cannot accommodate straight bridges. The skew angle can be defined as the angle between the normal to the centerline of the bridge and the centerline of the abutment or pier cap as described in Fig. 1.

The design of highway bridges in the United States conforms to the American Association of State Highway and Transportation Officials (AASHTO) procedures, either to the Standard Specifications for Highway Bridges (2002) prior to 2007 – thereafter referred to as AASHTO Standard [1], or to the current Load and Resistance Factor Design (LRFD) Specifications (2014) – thereafter referred to as AASHTO LRFD [2]. The current AASHTO procedures do not consider the effect of railings that are built integrally with the bridge deck, and only AASHTO LRFD accounts for skewness in the evaluation of the load-carrying capacity of bridges. Therefore, this study investigates the combined effect of railings and skew angle in resisting highway loading and increasing the load-carrying capacity of reinforced concrete slab bridges.

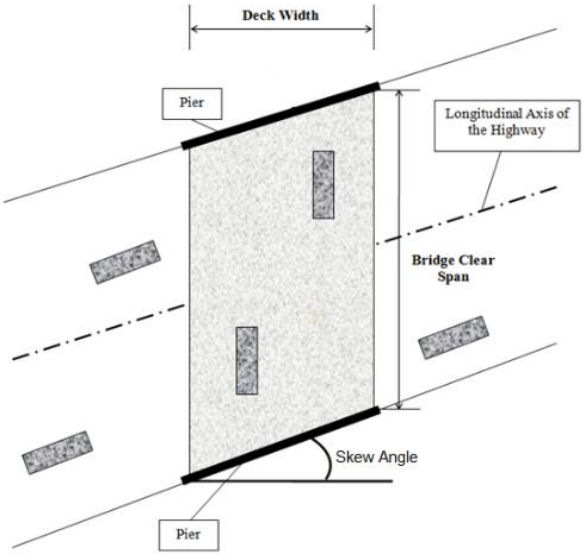

Fig. 1 Description of skewed bridge.

Several studies were conducted on the influence of sidewalks and railings on wheel load distribution in steel and prestressed girder bridges which was shown to increase the stiffness of the superstructure and improve the load-carrying capacity of these bridges [3]-[4]-[5]-[6]-[7].

A parametric study of straight, single-span, multi-lane (1 to 4 lanes) simply-supported reinforced concrete slab bridges, using finite-element analysis (FEA) was also reported [8]. Results indicated that AASHTO Standard moments overestimate the FEA moments for short spans, one-lane bridges and agreed with FEA moments for short spans in combination of two or more lanes. Also, AASHTO Standard underestimates the FEA moments for longer spans. As for AASHTO LRFD procedure, it overestimates FEA moments for all bridge cases. This study was extended to study the influence of skew angle on the same concrete slab bridges [9]. The ratio between the FEA longitudinal moments for skewed and straight bridges was almost one for bridges with skew angle less than 20 degrees. This ratio decreased to about 0.75 for bridges with skew angles between 30 degrees and 40 degrees, and further decreased to about 0.50 skew angle of the bridge increased to 50 degrees. Further, a study investigated the influence of one standard railing built integrally on either one or both edges of the slab deck, for the same straight bridges [10]. The results indicated that placing two railings on the bridge slab, AASHTO Standard overestimated the FEA moments by 100% for one-lane bridges, and by 20% for bridges with two or more lanes, while AASHTO LRFD overestimated the FEA moments in all bridge cases by 150% for one-lane, 70% for two-lanes, and a 30% for three- and four-lanes. Finally, a preliminary study considered the combination of railings and skewness on the concrete slab bridges previously analyzed for the cases of one and two lanes [11]. With no railing, AASHTO Standard generally tends to give similar results to the FEA slab moments for skew angle up to 20 degrees. As skew angle increases, AASHTO overestimation increases till it reaches 100% for bridges with skew angle of 50 degrees. Also, generally AASHTO overestimation is higher for one-lane bridges as compared to two-lane bridges and it decreases with the increase in span length. Adding two railings, AASHTO overestimates FEA moments for all bridge cases and this overestimation increases with the increase in skew angle reaching 140% for a skew angle of 50 degrees. Further, AASHTO LRFD overestimates the FEA slab moments in almost all bridge cases with or without railings. This overestimation increases with the increase in the skew angle and it is most significant for bridges with two railings and a skew angle of 50 degrees. For straight bridges with no railings, AASHTO LRFD overestimates the FEA slab moments by about 50% for one-lane bridges and about 30% for two-lane bridges. When the skew angle increases to 50 degrees, AASHTO LRFD overestimates the FEA slab moments by about 125% for one-lane bridges and about 100% for two-lane bridges. When two railings are present, and for straight bridges, the AASHTO LRFD overestimation of the FEA slab moments becomes more significant reaching an average high of 150% in one-lane bridges or 70% in two-lane bridges. As for bridges of skew angle of 50 degrees this overestimation reaches its maximum values and is 190% for one-lane bridges and 140% for two-lane bridges.

This paper builds on the previously published research, namely in [8]-[9]-[10]-[11], by performing a parametric study investigating the influence of railings and skweness on wheel load distribution in simply-supported, one-span, three- and four-lane concrete slab bridges. The FEA slab moments will be assessed with AASHTO Standard and LRFD, as well as with the reference straight bridge cases without railing.

AASHTO STANDARD AND LRFD PROCEDURES

For simply-supported concrete slab bridges, AASHTO Standard [1] suggest three approaches in determining the live-load bending moment but only one procedure is used in this study that was compared with the finite-element analysis results.

$$M = 13{,}500S \quad for\ S \le 15m \tag{1a}$$

or

$$M = 1{,}000(19.5S - 90) \quad forS > 15m \tag{1b}$$

where:
S = span length (m)
M = longitudinal bending moment per unit width (N-m/m)

AASHTO Standard Section 3.2.6 suggests that slab bridges with a skew angle less than 30 degrees be designed as a typical slab at right angles, or as straight bridges, with no modifications. However, if the skew angle exceeds 30 degrees, AASHTO suggests the use of an alternate superstructure configuration.

AASHTO LRFD [2] Section 4.6.2.3 provides an equivalent strip width procedure to design reinforced concrete slab bridges that is comparable to procedures specified in the AAHSTO Standard. However, the AASHTO LRFD Section 3.6.1.2 requires the use of HL93 (addition of HS20 Truck plus lane loading) live loading. This approach is to divide the total bending moment by an equivalent width to obtain a statically design moment per unit width. The equivalent width

"*E*" of longitudinal strips per lane for both shear and moment is determined using the following formulas:

The width for one lane loaded is:

$$E = 250 + 0.42\sqrt{L1 \times W1} \quad (2)$$

while the width for multi-lanes loaded is:

$$E = 2{,}100 + 0.12\sqrt{L1 \times W1} \quad (3)$$

where:

M = longitudinal bending moment per unit width (N-m/m)

E = equivalent width of longitudinal strips per lane (mm)

L1 = span length (mm), the lesser of the actual span or 18,000 mm

W1 = edge-to-edge width of the bridge (mm) taken to be the lesser of the actual width or 18,000 mm for multi-lane loading, or 9,000 mm for single-lane loading.

For skewed bridges, AASHTO LRFD 4.6.2.3-3 reduces longitudinal force effects by a factor "*r*" which is a function of the skew angle:

$$r = 1.05 - 0.25\tan\theta \le 1.\ldots \quad (4)$$

where θ is the skew angles in degrees.

The current AASHTO procedures (Standard or LRFD) do not consider the influence of railings that are built integrally with the bridge deck on the increase of the bridge stiffness and its load-carrying capacity.

BRIDGE CASES AND LOADING

Typical simply-supported one-span, three-lane and four-lane, straight and skewed reinforced concrete slab bridge cases were analyzed in this study, without and in the presence of integral railings. Four span lengths were considered, 7.2, 10.8, 13.8, and 16.2 m (24, 36, 46, and 54 ft) with corresponding slab thicknesses of 450, 525, 600, and 675 mm (18, 21, 24, and 27 inches), respectively. The lane width was assumed to be 3.6 m (12 ft) and therefore the overall slab widths were taken as 10.8 m (36 ft) for three lanes and 14.4 m (48 ft) for four lanes. Six skew angles varying between 0° and 50° by increments of 10° were considered. A straight bridge is defined as having a 0° skew angle. Standard railings, 200 mm (8 inches) wide and 760 mn (30 inches) high above roadway, were placed integrally on both sides of the slab edges (labeled as R2). Straight bridges without railings were first analyzed and considered as the reference cases (labeled as R0). Figure 2 shows a typical cross-section and plan layout of a 13.8 m (46 ft) span, three-lane bridge case, with 30° skew angle and railings placed on both edges of the slab deck.

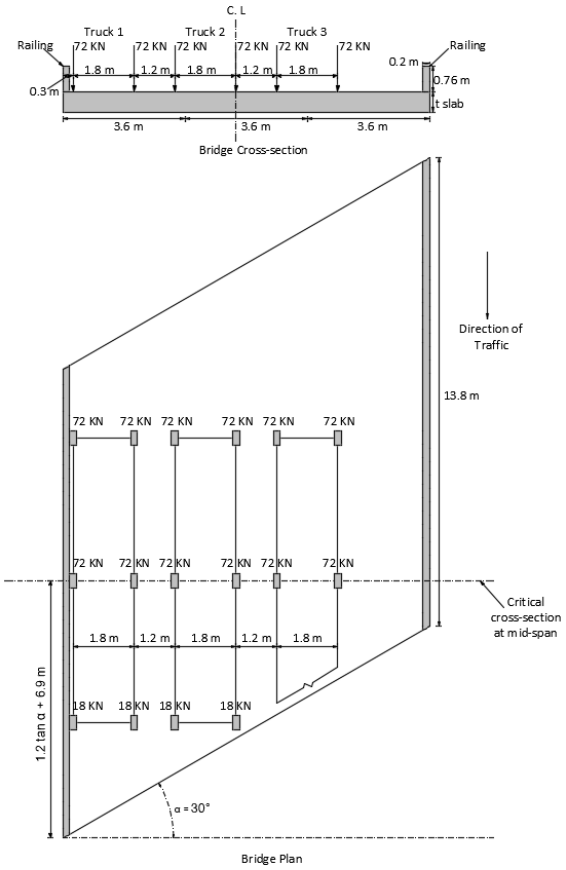

Fig. 1 Typical cross-section and layout for a 13.8 m (46 ft) span, three-lane, 30 degrees skewed bridge with railings, subject to HS20 Edge loading condition.

The bridge cases considered were subjected to AASHTO HS20 design trucks assumed to be traveling in the same direction placed longitudinally and transversally to produce maximum moments. For HS20 loading, the line wheel loads are 18 KN (4 Kips), 72 KN (16 Kips), and 72 KN (16 Kips) with axle spacing of 4.2 m (14 ft).

The longitudinal location of HS20 axle loads that produce maximum positive moment in one-span loading condition bridges was placed such that the centerline of bridge aligned with the location of centerline halfway between the resultant load of the truck and the middle axle. However, a previous study reported that the difference between placing the middle axle aligned with the mid-span versus the actual location mentioned above was negligible in determining the maximum bending moment in concrete slab bridges, which will therefore be adopted in this study [8]. Transversely, an Edge loading condition was applied, where the first design truck was placed close to one edge of the slab, such that the center of the left wheel of the left most truck is

positioned at 0.3 m (1 ft) from the left edge of the slab, and the other trucks were placed side-by-side with a distance 1.2 m (4 ft) between the adjacent trucks in order to produce the worst live loading condition on the bridge [8]. It is also worth noting that only the left-most truck was centered longitudinally, while adjacent trucks were aligned with the edge truck as shown. This condition resulted in slightly higher moments than for the case where each adjacent truck was centered longitudinally in its own lane [9]. Figure 2 shows the Edge loading condition for the bridge case described earlier.

The material properties used in modeling the highway bridges were normal-strength reinforced concrete. The compressive strength of the concrete was 27,500 kPa (4,000 psi), the modulus of elasticity was 25×10^6 kPa (3.6×10^6 psi), and Poisson's ratio was 0.2. Grade 60 reinforcing steel could be assumed in the design of slab reinforcement, but the FEA models did not include such property in the analysis.

FINITE ELEMENT MODELING AND RESULTS

A total of 96 slab bridge cases were investigated using the FEA using the general computer program SAP2000 [12]. The bridge discretization was tested in previous studies where shell elements with six degrees of freedom at each node were used to model the slab [8]-[9]. A typical four-node square element size of 0.3x0.3 m (1x1 ft) was adopted and for the slab discretization four-node quadrilateral and three-node triangular elements were additionally used at the supports to accommodate for skewness. Railings placed both edges of the slab were modeled as space frame elements placed "eccentrically" along the slab edges with the second moment of area calculated about its base. This was based on previous studies which investigated the appropriate railing modeling on straight concrete slab bridges [10]-[11]. This study considered all elements to be linearly elastic and the analysis assumed small deformations and deflections. Figure 3 shows a typical FEA model for the bridge case described earlier subjected to AASHTO HS20 Edge loading condition.

The FEA results are reported in terms of the maximum longitudinal bending moments at critical cross-section locations in the concrete slab bridges, shown in Fig. 3. The FEA results for skewed bridges with railings were compared with straight reference bridge cases without railings (R0- 0 degrees) as well as with AASHTO Standard [1] and LRFD [2] procedures. Figure 4 shows sample plots of the FEA longitudinal bending moment at the critical sections for 13.8 m (46 ft) span, three-lane bridge cases with the various railing configurations (R0 for no railing; and R2 for two railings), and select skew angles (only 0, 30, and 50 degrees for clarity) subject to Edge HS20 loading conditions. The corresponding AASHTO moments are also plotted in the figure. It is worth mentioning that the maximum FEA longitudinal moments in Fig. 4 for the concrete slabs was defined as the first peak value occurring after the maximum value at the leftmost edge which is assumed to be resisted by the edge beam and/or railing when present.

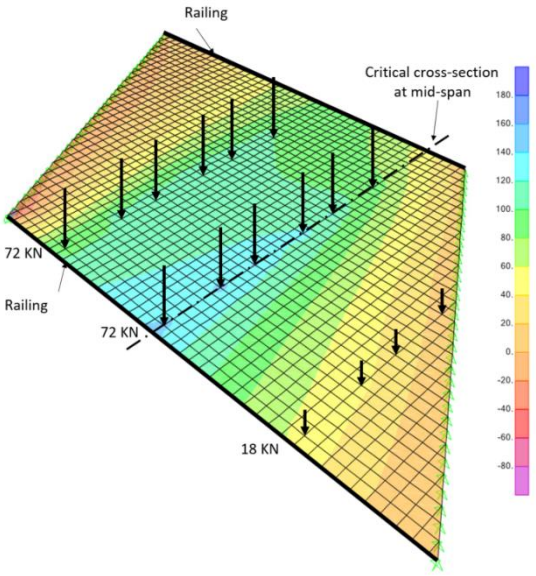

Fig. 2 FEA discretization and moments (KN-m/m) in a 13.8 m (46 ft) span, three-lane, 30° skewed bridge with railings, subject to HS20 Edge loading condition.

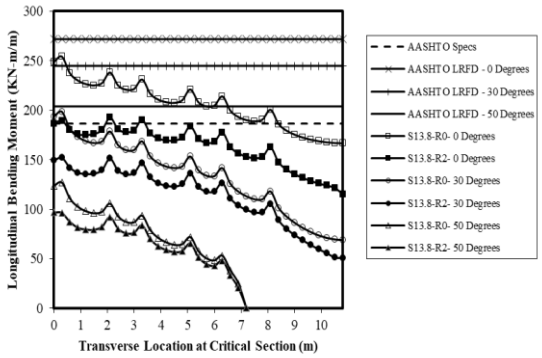

Fig. 3 FEA and AASHTO Standard (Specs) and LRFD moments for 13.8 m (46 ft) span, three-lane skewed bridges with railings and reference straight bridges without railing.

FEA RESULTS VS. AASHTO PROCEDURES

Table 1 summarizes the increase or decrease in predicting the bending moments in the concrete slabs when comparing the maximum FEA with the AASHTO moments for all bridge cases analyzed.

Using Table 1, it can be observed that, for short-span bridge cases with no railing, AASHTO Standard generally tends to give similar results to the FEA slab moments for skew angle up to 20 degrees, and overestimates the FEA moments by about 20 to 50%

for skew angle up between 30 and 50 degrees. For longer span bridge cases with no railing, AASHTO Standard generally tends to underestimate to the FEA slab moments by about 10 to 35% for skew angle up to 20 degrees, and gives similar results or overestimates the FEA moments by about 10 to 45% for skew angle up between 30 and 50 degrees. Adding two railings, AASHTO Standard overestimates FEA moments for almost all bridge cases and this overestimation increases with the increase in skew angle reaching about 60% for short-span bridges with skew angle of 50 degrees; only in few long-span bridge cases with two railings and for skew angles up to 20 degrees, then AASHTO gives similar results or underestimates the FEA moments by about 10 to 20%.

Table 1 Comparison of FEA Maximum Moments and AASHTO Moments

	10.8	152	119	183	130	103	171	146
	13.8	213	175	261	181	151	245	186
	16.2	261	225	333	223	194	312	226
4	7.2	91	73	93	76	60	87	97
	10.8	158	127	173	132	106	162	146
	13.8	221	186	258	186	157	242	186
	16.2	271	239	333	229	203	312	226
Number of Lanes	Span Length (m)	FEA Maximum Longitudinal Moments and LRFD Moments (KN-m/m)						AASHTO Standard (KN-m/m)
		40 Degrees			50 Degrees			
		R0	R2	LRFD	R0	R2	LRFD	
3	7.2	63	51	86	48	39	77	97
	10.8	103	84	160	80	63	143	146
	13.8	144	123	228	111	92	204	186
	16.2	180	158	292	138	119	260	226
4	7.2	63	51	81	48	39	72	97
	10.8	104	85	151	80	63	135	146
	13.8	146	125	226	110	91	202	186
	16.2	183	162	292	138	120	260	226

Also with reference to Table 1, it can be deduced that AASHTO LRFD generally overestimates the FEA slab moments in almost all bridge cases with or without railings, and gives similar results in a few cases without railing. For short-span bridge cases with no railing, AASHTO LRFD generally tends to give similar results to the FEA slab moments for skew angle up to 20 degrees, and overestimates the FEA moments by about 15 to 40% for skew angle up between 30 and 50 degrees. For longer span bridge cases with no railing, AASHTO LRFD overestimates the FEA slab moments by about 10 to 20% for skew angle up to 20 degrees, and by about 25 to 50% for skew angle between 30 and 50 degrees. Adding two railings, AASHTO LRFD overestimation of the FEA moments increases with the increase in skew angle from about 20% for straight bridges with no skewness to about 50% for bridges with skew angle of 50 degrees.

It is worth noting that generally AASHTO overestimation is higher for three-lane bridges as compared to four-lane bridges except for high skew angles of 40 to 50 degrees when the results of three- and four-lane bridges become similar.

FEA RESULTS OF SKEWED BRIDGES WITH RAILINGS VS. REFERENCE BRIDGES

The maximum slab bending moments are summarized in Table 2 for all bridge cases in terms of ratios of FEA results for skewed bridges with railings to the corresponding reference straight bridges without railings. Table 2 shows that the maximum longitudinal slab moment reduces with the increase in skew angle and it is more pronounced for bridges with two railings. For angle of skewness less than 20º, the reduction in the moment reaches 30% for bridges with two railings, and about none for bridges with no railing. For angle of skewness equal to 20º, the reduction in the moment reaches 30% for bridges with two railings, and about 10% for bridges with no railing. For angle of skewness equal to 30º, the reduction in the moment reaches 40% for bridges with two railings, and about 25% for bridges with no railing. For angle of skewness equal to 40º, the reduction in the moment reaches 50% for bridges with two railings, and about 40% for bridges with no railings. For angle of skewness equal to 50º, the reduction in the moment reaches 65% for bridges with two railings, and about 55% for bridges with no railing.

It is worth noting that generally the reduction in FEA moments due to skewness and railings is slightly affected by the number of lanes or span lengths considered.

SUMMARY AND CONCLUSIONS

AASHTO Standard [1] and AASHTO LRFD [2] empirical equations do not account for the presence of railings as integral parts of a bridge slab, and these elements are neglected during the design stage, and only AASHTO LRFD considers skewness to reduce the designs slab moments.

A parametric study using finite-element analysis was performed to investigate the influence of railings and skewness on the longitudinal slab moments in simply-supported, one-span, three- and four-lane concrete slabs bridges. The bridge parameters considered were the span length, number of lanes, railings on both edges, and skew angle. The FEA

moments were assessed with AASHTO procedures and with reference bridge cases without railing.

The study concluded that the presence of railings increases the load carrying capacity of the bridges if they are modeled as integral parts of the slab, and that the slab moments reduce with the increase in the increase of skew angle. Further the influence of railings and skew angle is cumulative and becomes significant with high skewness and two railings. It can also be noted that integral railings can be used as one alternative strengthening technique to upgrade already existing bridges that require rehabilitation or upgrading, or if heavier loads are foreseen.

ABSTRACT

The presence of railings or parapets acting integrally with the concrete deck placed on steel girders has the effect of stiffening and therefore altering the lateral wheel load distribution on highway bridges. The American Association of State Highway and Transportation Officials (AASHTO) Standard Specifications for Highway Bridges and AASHTO LRFD Bridge Design Specifications procedures do not account for the presence of railings when evaluating the load-carrying capacity of highway bridges. This paper presents a parametric study using 3D finite element analysis to investigate the influence of railing stiffness on one-span, two-lane steel girder bridges. Railings of different sizes were placed on one or both sides of the bridge deck, in combination with various span lengths and girders spacing. AASHTO HS20 design trucks were placed longitudinally and transversally in order to produce maximum longitudinal bending moments in the steel girders. The wheel load distribution obtained from finite element analysis at the critical section of each bridge were compared with the AASHTO procedures and with reference cases for bridges without railing. This study confirmed that the presence of concrete railings modeled and built integrally with the deck tends to stiffen the bridge superstructure. Further, the study quantified the effect of railing in increasing the load-carrying capacity of steel bridges. The results of this research will therefore assist structural engineers in better designing new steel girder bridges and/or evaluating more precisely the load-carrying capacity of existing bridges with railings of different sizes. Bridge engineers can consider adding or stiffening railings/parapets as a practical method for strengthening existing steel girder bridges.

Keywords: Steel girder bridges, Railings or parapets stiffness, AASHTO procedures, Finite-element analysis, Wheel load distribution factor, Load-carrying capacity

INTRODUCTION

A common type of highway bridge deck is a reinforced concrete slab placed on steel I-beams that is referred to as a steel girder bridge. The analysis and design of highway bridges in the United States must conform to the American Association of State Highway and Transportation Officials (AASHTO) procedures, either to the Standard Specifications for Highway Bridges (2002) prior to 2007 – thereafter referred to as AASHTO Standard [1], or to the current Load and Resistance Factor Design (LRFD) Specifications (2014) – thereafter referred to as AASHTO LRFD [2]. Typically, the analysis of a three-dimensional (3D) bridge superstructure is reduced to the analysis of a two-dimensional (2D) single girder by using a wheel load distribution factor (DF). The current AASHTO wheel load distribution factors (Standard or LRFD) do not consider the influence of raised sidewalks and/or railings that are built integrally with the bridge deck, nor their effect on the increase of the bridge's stiffness and its load-carrying capacity.

A previous study reported the results of a parametric study that investigated, using finite element analysis (FEA), of various modeling techniques on one-span, two-lane, simply supported, composite steel girder bridges without the presence of sidewalks or railings [3]. In this study, the span length and girder spacing were varied within practical ranges, and the FEA results were used to calculate the longitudinal bending moments and wheel load distribution factors in the steel girders for the composite slabs, which were compared with AASHTO procedures. A follow-up study extended the latter analysis to investigate the influence of sidewalks and railings of standard sizes on wheel load distribution for the same bridges [4]. The presence of sidewalks and railings was shown to increase the stiffness of the superstructure and improve the load-carrying capacity of steel bridges by as much as 30%.

Another study investigated the influence of secondary elements and deck cracking on the lateral load distribution of steel girder bridges [5]. The presence of secondary elements such as lateral bracing and parapets produces load distribution factors up to 40% lower than the AASHTO LRFD values. Other work investigated the effect of parapets

and bridge aspect ratio on live-load moment distribution in bridge girders [6]. The finite element analysis was used to investigate 34 two-span continuous bridges with different skew angles and overhang lengths. The presence of parapets was shown to reduce the wheel load distribution factors by as much as 36% and 13% for exterior and interior girders, respectively. Another research reported the parapet strength and contribution to live-load response for permit super-load passages were tested [7]. The results of this study showed that girder distribution factors (GDFs) can be decreased by as much as 30%, depending on the stiffness of the girders and the transverse truck position if the parapets are included in the analysis. The effect of secondary elements on load distribution in prestressed bridge girders was examined showing the effect of including barriers (railings) in calculating the wheel load distribution and bending moments in girders [8].

This paper builds on the previously published research, namely in [3]-[4], by performing a parametric study investigating the influence of railing stiffness on wheel load distribution in simply-supported, one-span, two-lane steel girder bridges. The results of 240 bridge cases that are modeled using FEA are presented in this paper. The various bridge parameters investigated in this study are the span length, girder spacing, and various railings stiffness and configurations, subject to HS20 truck loadings positioned transversally and longitudinally in order to produce the maximum longitudinal live load bending moments. Parapets or railings are assumed to be placed on either edge or both edges of the bridge deck, built integrally with the concrete slabs that is placed over steel girders under composite action. The effect of railing stiffness on the maximum live load wheel load distribution factors are assessed by calculating and comparing the FEA bending moments with both AASHTO Standard and LRFD, as well as with the reference bridge cases without railing.

AASHTO STANDARD AND LRFD PROCEDURES

The AASHTO Standard [1] specifications specify the load distribution factor for a steel girder to be a function of the girder spacing only. The use of distribution factors reduces the three-dimensional (3D) bridge deck analysis to a two-dimensional (2D) beam analysis and design process subject to AASHTO HS20 loadings. Typically, AASHTO design wheel loads are positioned on a 2D girder using influence lines to produce the maximum design live load moment, which is then multiplied by an empirical wheel load distribution factor (DF) such as S/5.5, where S is the girder spacing in feet (S/1676, where S is in millimeters) – thereafter referred to as "S/5.5" formula. If the girder spacing is greater than 14 ft (4.27 m), AASHTO recommends the use of simple beam distribution for estimating the wheel load distribution factor. This AASHTO Standard procedure has been criticized for being conservative due to its simplistic load distribution factors.

The AASHTO LRFD [2] specifications introduced relatively new wheel load distribution factors based on published research in the last few decades. AASHTO LRFD wheel load distribution formulae presented in Table 4.6.2.2.2b-1 account for parameters such as span length, girder spacing, and cross-sectional properties of the bridge deck. The wheel load distribution factor for bending moment in two-lane steel girder bridges is, in Imperial units:

$$g = 0.075 + \left(\frac{S}{9.5}\right)^{0.6}\left(\frac{S}{L}\right)^{0.2}\left[\frac{K_g}{12.0Lt_s^3}\right]^{0.1} \quad (1a)$$

The equivalent equation in SI units is:

$$g = 0.075 + \left(\frac{S}{2{,}900}\right)^{0.6}\left(\frac{S}{L}\right)^{0.2}\left[\frac{K_g}{Lt_s^3}\right]^{0.1} \quad (1b)$$

where:

S = girder spacing (ft, $3.5 \le S \le 16.0$) or (mm, $1{,}100 \le S \le 4{,}900$)

L = span length of beam (ft, $20 \le L \le 240$) or (mm, $6{,}000 \le L \le 73{,}000$)

K_g = longitudinal stiffness parameter (in^4, $10{,}000 \le K_g \le 7{,}000{,}000$) or ($mm^4$, $4x10^9 \le K_g \le 3x10^{12}$) $= n\,(I + A\,e_g^2)$

n = modular ratio between beam and deck material

I = moment of inertia of beam (in^4 or mm^4)

A = girder gross area (in^2 or mm^2)

e_g = distance between the centers of gravity of the basic beam and deck (in or mm)

t_s = depth of concrete slab (in, $4.5 \le t_s \le 12.0$) or (mm, $110 \le t_s \le 300$)

Equation (1) is recommended for highway bridges with at least two lanes, composite or non-composite, single- and multi-span steel girder bridges. Even though this equation was recommended for bridge decks with at least four girders, the presence of three girders in a bridge deck was also investigated in this paper and the FEA results were evaluated and compared with Eq. (1).

BRIDGE CASES AND LOADING

Typical one-span, simply supported, two-lane straight steel girder bridges were selected for this parametric FEA investigation. The bridge deck consisted of a 7.5 inches (190 mm) reinforced concrete slab thick supported by structural steel girders (W36x160). The various span lengths "*L*" considered in this study were 40, 60, 80, 100, and 120 ft (12, 18, 24, 30, and 36 m). The girder spacing "*S*" was set at 6, 8, and 12 ft (1.8, 2.4, and 3.6 m). A standard lane width of 12 ft (3.6 m) was used with a shoulder width of 4 ft (1.2 m), and the overall bridge

slab width was 32 ft (9.6 m) for two lanes with a shoulder on each side. These dimensions accommodate the possible presence of sidewalks and/or railings on the bridge deck. A typical bridge cross-section with 6 ft (1.8 m) girder spacing is shown in Fig. 1.

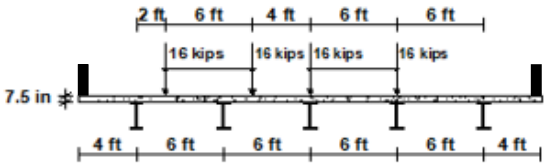

Fig. 1 Typical two-lane bridge cross-section with standard railings on both edges (x1, 2R) and HS20 trucks loading.

A reinforced concrete railing or parapet, 8 inches (200 mm) thick by 30 inches (760 mm) high, was selected as the standard railing (labeled as x1) and placed on the left, right, and on both sides of the deck (labeled respectively as RL, RR, and 2R) for all bridge combination parameters considered, as shown in Fig. 1 for the case (2R). Four additional railing sizes were considered in this study by varying the stiffness to half, double, triple and quadruple the standard railing stiffness (labeled respectively as x0.5, x2, x3, and x4), and all railings cross-sections are shown in Fig. 2. It was assumed that the railings were properly reinforced and connected integrally to the bridge deck in order to transmit the shear forces, bending moments, and to act integrally with the superstructure. Reference bridge decks with no railing were also analyzed using for comparative analysis (labeled as NoR).

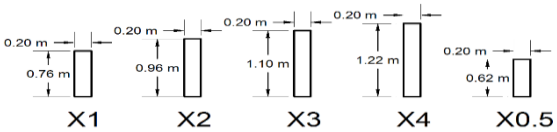

Fig. 2 Various railing sizes (x1, x2, x3, x4, x0.5).

The bridge live loadings considered in this investigation were limited to the AASHTO Standard [1] of either applying AASHTO HS20 design truck or a train of HS20 trucks depending on the span length. The single HS20 truck has a total weight of 72 Kips (324 kN), distributed over two rear axles of 32 Kips (144 kN) each and one front axle of 8 Kips (36 kN), with a distance of 14 ft (4.2 m). For the train of trucks, HS20 trucks were placed longitudinally in each lane of a given bridge, with a spacing of 30 ft (9 m) separating each of the trucks. Only one truck per lane can fit on a given bridge, and the design truck or train of trucks using influence lines in order to achieve the most severe live loading conditions. In all cases, the trucks in multiple lanes assumed to be traveling in the same direction. Transversally, the AASHTO HS20 design trucks were positioned side-by-side on the bridge superstructures with a distance of 4 ft (1.2 m) between the loading points. Note that the transverse position of the trucks was selected in order to produce the most severe loading conditions on the bridge to result in the maximum bending moment in the critical girder, as shown for the 6 ft (1.8 m) girder spacing in Fig. 1.

Typical material properties used in modeling the bridge superstructure were normal-strength reinforced concrete with compressive strength of 4,000 psi (27.5 MPa), modulus of elasticity of 3.6×10^6 psi (24.8 GPa), and Poisson's ratio of 0.20. The modulus of elasticity of steel beams were selected to be 29×10^6 psi (200 GPa).

FINITE ELEMENT MODELING

The 3D-FEA model and mesh discretization adopted to analyze the 240 bridge cases considered is based on previous studies reported earlier [3]-[4] using the general FEA program SAP2000 [9]. This study considered all elements to be linearly elastic and the analysis assumed small deformations and deflections.

The concrete slab was modeled using quadrilateral 2x2 ft (0.60x0.60 m) shell elements (SHELL, with 6 degrees of freedom at each node) and the steel girders were idealized as space-frame elements (FRAME, with six degrees of freedom at each node). The railings were also modeled as concentric space-frame elements with a moment of inertia and stiffness equivalent to an eccentric element applied on top of the slab [4]. Hinges were assigned at one bearing location and rollers at the other to simulate the simple support conditions. AASHTO HS20 wheel loads were applied at isolated nodes, located longitudinally and transversally in order to produce maximum longitudinal bending moments. Figure 3 shows a typical 3D-FEA model for a two-lane bridge with span length of 80 ft (24 m) and girder spacing of 6 ft (1.8 m) subjected to AASHTO HS20 truck loading.

The 3D-FEA results reported are stresses or moments for the slab shell elements and moments for the girders and railings frame elements. The moments in the girders were calculated using two parts: (a) the bending moment contribution of the tributary or effective concrete slab, and (b) the bending moment in the steel girder element. Figure 4 shows the longitudinal bending moment distribution in all girders (no slab contribution) and railings for the same bridge case shown in Fig. 3.

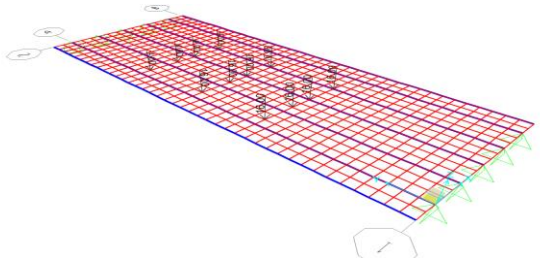

Fig. 3 Typical 3D-FEA model of a two-lane bridge with standard railings on both edges (x1, 2R) and HS20 trucks loading.

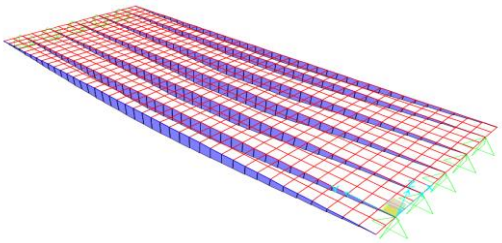

Fig. 4 Typical girders moment diagrams in a two-lane bridge with standard railings on both edges (x1, 2R) and HS20 trucks loading.

SUMMARY OF RESULTS

The maximum FEA moments from each and all girders, with the corresponding moments contributed from the slabs and railings, are obtained for all the 240 bridge cases analyzed. The presence of railings were considered as a part of the concrete section that contributed to the exterior girders in resisting wheel loads which tends to overestimate those moments as compared to interior girders. However, when considering girder and slab without railings, the moments in the critical interior girder will be larger than in exterior girders, and will therefore be considered as the effective moments used for design.

Table 1 shows a typical summary of those moments for the 80 ft (24 m) span, 6 ft (1.8 m) girder spacing with standard railings (x1) at either or both sides of the bridge deck; the case with no railing is also shown for reference. The maximum FEA moments in the critical interior girder (M_{max}) for the latter bridge cases can be obtained for each railing configuration (NoR, RL, RR, and 2R) by combining girder and slab moments; this is shown in the "Max-Total" value in the last column of the table. It is also worth noting that the total moment summed from all girders, slabs, and railings, or "Total-Total", is the same for all railings configurations, and is equal to four times the maximum statical girder moment (M_o) obtained from 2D-beam analysis with one line of wheel loads applied, for all the two-lane bridges.

Table 1 FEA moments in girders, slabs, and railings for two-lane bridges with 80 ft span, 6 ft girder spacing, and standard railings (x1).

The wheel load distribution factor (DF) from FEA was calculated by dividing the maximum FEA moment in the critical interior girder (M_{max}), considering the combination of moments from steel girder and concrete slab, by the maximum girder moment (M_o), or DF = M_{max}/M_o. This FEA DF for interior girders for the bridge cases with various configurations and sizes of railings will be compared with the DF from AASHTO Standard formula ("S/5.5") and LRFD Eq. (1), as well as with the reference bridges without railings, in order to determine the effect of these elements on the bridge superstructure. The maximum statistical girder moment (M_o) and FEA wheel load DF for interior girders are summarized in Table 2 for the two-lane bridge cases considered, for all span lengths and girder spacing analyzed with standard railings (x1) at either or both sides of the bridge deck, including the case with no railing as a reference. The FEA wheel load DF are also plotted with the span lengths in Fig. 5, along with AASHTO Standard formula ("S/5.5") and AASHTO LRFD Eq. (1) for the two-lane bridges with 6 ft (1.8 m) girder spacing and standard railing stiffness (x1). Finally, Table 3 shows the maximum interior AASHTO and FEA DF for all 240 bridge cases, with the various railings stiffness considered in this study.

ANALYSIS OF RESULTS

For the particular bridge cases shown in Table 1 of the two-lane bridges with 80 ft (24 m) span and 6 ft (1.8 m) girder spacing, the FEA results shows that the contribution of bending moment from the concrete slab is about 5% to the overall total girder bending moment when there is no railing on the bridge. It was also observed that this percentage contribution ranges from about 5% to 15% for other two-lane bridge cases considered with no railing. However, when introducing railing or parapet on one or both sides of the bridge deck, the concrete slab and railing contribute largely to the total bending moment of the exterior girder in bridges, which can reaches about 50% with the standard railing stiffness (x1) for the bridge cases shown in Table 1. The FEA moments results in exterior girders showed that the percentage of the deck contribution (slab and railing) to the overall moments increased due to changes in railing stiffness and span lengths, but not with girder spacing, ranging from about 25% to 35% for (x0.5), 35% to 50% for (x1), 40% to 65% for (x2), 40% to 75% (x3), and 45% to 80% for (x4).

In this study, since the AASHTO HS20 trucks were placed 2 ft (0.60 m) from the left outside girder, the maximum bending moment predicted to occur in either one of the two left side girders, except for the shortest span, where in the case of 6 ft (1.8 m) girder spacing, the maximum was always at the center girder. Therefore, when the railings were placed on the left side or on both sides of the bridge, the maximum bending moment occurred in the left exterior girder when adding the contribution of the railing but, as discussed earlier, the effective critical girder will be an interior one. As a result, the wheel load DF to be used in the girders will be identified based on the maximum moment occurring in the interior critical girder.

This FEA maximum design moment or FEA-DF will therefore be compared with AASHTO procedures/equations, with and without railings. Also, the maximum FEA-DF for cases with railings on either edge or both edges will be compared with the reference FEA-DF cases without railing for all railings stiffness considered. Note that for exterior girders, the railings when present should be designed to take the large moments attracted to those stiffening elements.

FEA results vs. AASHTO procedures

As shown in Table 3, AASHTO Standard [1] formula is highly conservative when compared with the FEA DF without railing which was also previously reported [3] for all the two-lane bridge cases considered. This will be even more the case with any railing size. This study will therefore focus on comparing the FEA DF with AASHTO LRFD [2] Eq. (1), where a good correlation in the pattern of results was observed as shown in Fig. 5. Using Table 3, the following general observations can be made:

- No railing (NoR): FEA DF were smaller than Eq. (1) by about 10% for spans up to 80 ft (24 m), and by about 5% for spans between 80 and 120 ft (24 to 36 m).
- Railing on one side (Largest of RL or RR): FEA DF were smaller than Eq. (1) by about: 10% for railing stiffness (x0.5), 15% for railing stiffness (x1) and (x2), and 20% for railing stiffness (x3) and (x4).
- Railings on both sides (2R): FEA DF were smaller than Eq. (1) by about: 20% for railings stiffness (x0.5), 30% for railings stiffness (x1), 45% for railings stiffness (x2), 50% for railings stiffness (x3), and 60% for railings stiffness (x4).

Influence of railings stiffness vs. reference base cases without railing

Using Table 3, the following general observations can be made:

- Railing on one side (Largest of RL or RR): FEA DF with one railing is reduced when compared to reference case without railing by an average of about: 5% and 10% for railing stiffness (x0.5) through (x4) for spans between 40 and 80 ft (12 to 24 m), and 10% and 20% for railing stiffness (x0.5) through (x4) for spans for spans between 80 and 120 ft (24 to 36 m).
- Railings on both side (2R): FEA DF with two railings is reduced when compared to reference case without railing by an average of about: 10% and 30% for railings stiffness (x0.5) through (x4) for spans between 40 and 80 ft (12 to 24 m), and 15% and 50% for railings stiffness (x0.5) through (x4) for spans for spans between 80 and 120 ft (24 to 36 m).

SUMMARY AND CONCLUSIONS

A parametric study using finite-element analysis was performed to investigate the influence of railing stiffness on wheel load distribution in simply-supported, one-span, two-lane steel girder bridges. The bridge parameters considered were the span length, girder spacing, and railings stiffness and configurations, subject to HS20 truck loadings positioned transversally and longitudinally in order to produce maximum girder bending moments.

The effect of railing stiffness on the maximum live load wheel load distribution factors were assessed by calculating and comparing the FEA moments or wheel load distribution factors with both AASHTO Standard and LRFD, as well as with the reference bridge cases without railing. The study confirmed that AASHTO Standard [1] formula is highly conservative when compared with the FEA DF without railing or with railings, and that FEA DF were smaller than AASHTO LRFD [2] Eq. (1) by about 5-10% with no railing, to about 20-50% for two railings with stiffness (x0.5) to (x4), depending on span lengths. The study also showed that the presence of one or two railings reduces the FEA-DF about 5-20% or 10-50%, respectively, depending on railings stiffness and span length. Such reduction in DF due to railings implies an increase in the bridge. Therefore, bridge engineers can consider adding, replacing, or stiffening railings/parapets as a practical method for strengthening existing steel girder bridges.

ABSTRACT

The aim of this study was to determine the suitability of three different configurations of beam type and analyze these beam type with variation of span lengths as well as its effects to bridge deck by considering maximum bending moment, shear force and deflection. This study focuses on single span bridge of TM-beam, I20-beam and U12-beam with varying span lengths of 30m, 28m and 24m. These pre-cast concrete beams were spaced equally. The bridge deck analysis was carried out by using STAAD.Pro software. Maximum bending moment, shear force and deflection were found from U12-beam, followed with TM-beam and I20-beam respectively. Thus, it can be concluded that I20-beam is the best option as compared to TM-beam and U12-beam. Apart from the beam shape, the span length also affects the bridge deck analysis, as the longer the span length, the values of bending moment, shear force and deflection will also increase. Note that, other factors should also be considered, namely; ease of construction, the amount of reinforcements, formworks, concrete and tendon. Nevertheless, the design choices are in the hand of the engineer and the final decision will still be in the hand of the client.

Keywords: Span length, Beam type, Bridge Deck, Analysis, STAAD.Pro

INTRODUCTION

Standard bridge beams have been developed to cover a wide variety of applications. Although there is a recognized range of spans for which each standard section is generally used, the fields for various types overlap and the final selection is normally based on experience relating to a specific situation. Currently, the common bridge beams in Malaysia are; TM-Beam, I-Beam and U-Beam. But the main selection of the type of beams for a bridge should be based on structural condition, functional, available of materials, effectiveness of cost, geometric requirements, geological condition, construction sequence as well as its aesthetic factor.

This paper discusses about the effect of three different configuration of beam types to the bridge deck analysis and analyze it further with span length variations. Comparisons were made in terms of maximum bending moment, shear forces and deflection. This study focused on single span bridge of TM-beam, I20-beam and U12-beam with varying span lengths of 30m, 28m and 24m. The bridges were modeled using STAAD.Pro [1] software. Bending moment and shear force results obtained during the analysis stage, leads to the reinforcement details during the design stage. The results were checked under the Ultimate Limit State (ULS) condition, whereas, the deflection was checked under the Serviceability Limit State (SLS) condition. The limits are vital in ensuring that the structure remains in elastic phase under loading [2].

METHODOLOGY

Overall, nine (9) simply supported bridge were modeled with varying span length of 30m, 28m and 24m. Three (3) types of beams shape were selected; TM-10 (T-beam), I-20 (I-beam) and U-12 (U-beam). Six (6) equally spaced concrete girders with 1.90m spacing (1.9m c/c). The girders support 180mm thick concrete deck and 100mm thick asphalt concrete premix. The abutments are supported by six (6) numbers of 1200mm diameter concrete piles of 16m length. Figure 1 and 2 illustrate the plan and longitudinal section of the bridge.

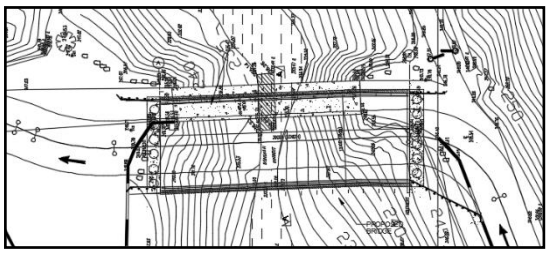

Fig.1: Plan view of the simply supported bridge

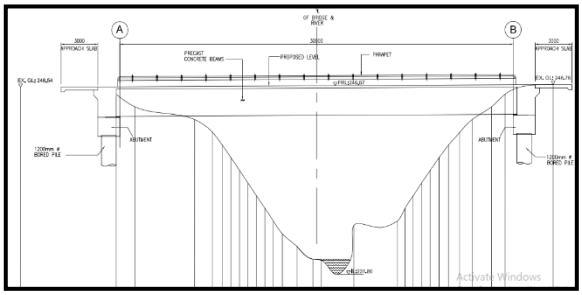

Fig.2: Longitudinal section of the simply supported bridge, crossing river channel

Section properties of the TM-10, I20 and U12 pre-cast concrete girders were taken from supplier catalogue and calculated further by using Integrated Bridge Design Software (SAM Leap 5). In this study, SAM was used to obtain the accurate section properties of TM-10, I20 and U12 pre-cast concrete girders. Figure 3 show the beam arrangements, whereas Fig. 4-6 show its typical sections.

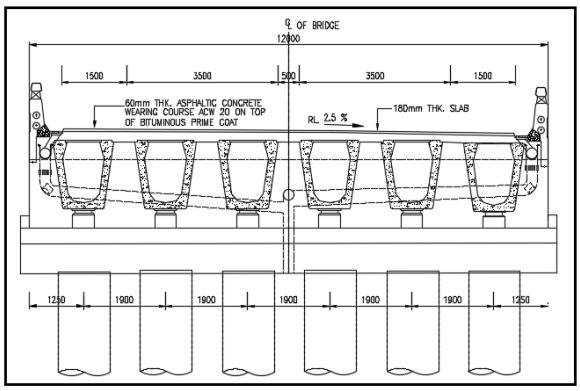

Fig.3: Beam arrangements

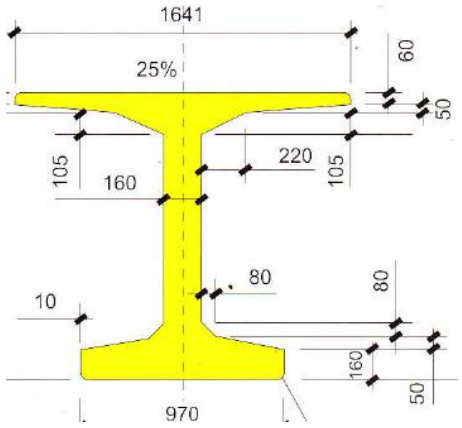

Fig.4: Typical section of TM-Beam

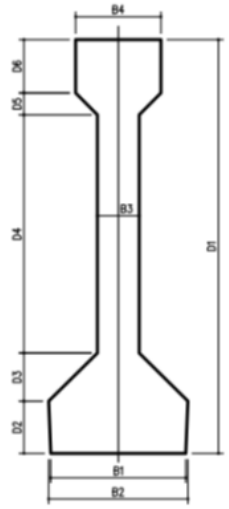

Fig.5: Typical section of I-Beam

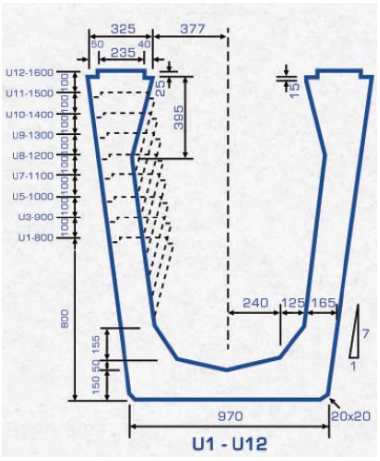

Fig.6: Typical section of U-Beam

The bridge superstructures comprise of precast concrete TM-10, I20 and U12 beams placed at 1.9m centre to centre and 180 mm thick cast in-situ reinforced concrete deck slab for the varying span lengths of 30m, 28m and 24m. The substructure consists of reinforced concrete abutments and piers/pile that are located outside the natural river profiles to improve water-flow and reduce scouring. Pier/pile type abutments that are located outside RS-wall are adopted for high approach road embankment to retain the horizontal earth pressure. As such, earth pressure is not considered in designing abutment column and abutment piles. Bank seat type abutment is adopted at the locations where the height of embankment is less than 3m. 1200mm diameter bored pile is used at the abutment with appropriate design loads. The whole structure is supported on 1200mm diameter bored pile for foundation system.

The modelling of the single span bridge was done by using STAAD.Pro V8i software. Three-dimensional (3D) model of single span bridge was adopted. The concrete slab (considered as plate) was supported by six (6) concrete longitudinal girders and abutment was modelled as shell element. Six (6) bored piles concrete were connected to each abutment with connectivity node. Figure 7 shows the 3D model of the single span bridge.

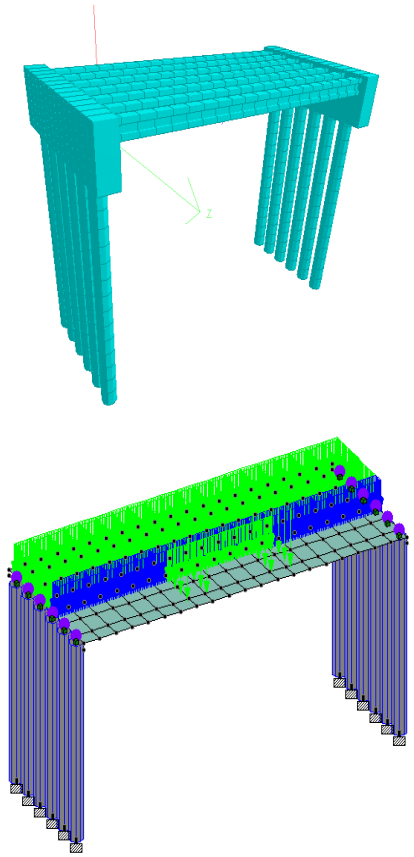

Fig.7: Three-dimensional model of the bridge

Grades of concrete used:

Location	Grade
Prestressed precast beams	C50
Parapets in-situ concrete	C40
Piers	C40
Pilecaps, deck slab, diaphragm beams	C40
Bored cast in-situ piles	C40

Grades of steel reinforcement used:

Steel type	Fy(N/mm^2)	E(kN/mm^2)
Mild Steel	250	200
High Yield Deform Type 2	500	200

The design was carried out in accordance with the design standards and specifications. The structure has been analyzed for self-weight, traffic load, and superimposed dead load. Local analysis due to concentrated wheel loads on deck slab has been done by using STAAD.Pro and STAAD BEAVA software. All loads considered in the analysis are applied in conjunction with the Design Statement and in accordance with BS 5400 [3] or BD 37/01 [4] whichever is relevant.

RESULTS AND DISCUSSIONS

Manual calculation was carried out to compare it with the Finite Element Analysis (FEA) of varying beam types and span lengths for validating the bridge models. To obtain the reliable data, only self-weight loading was considered for bending moment and shear force. Table 1, 2 and 3 show comparison results of manual calculation vs FEA.

Table 1: Manual calculation vs FEA: 30m span

Beam	Item*	Manual calc.	FEA	Diff. (%)
TM	BM	2694.86	2826.90	4.67
	SF	359.31	377.92	4.92
I20	BM	2690.99	2813.87	4.37
	SF	358.80	373.28	3.88
U12	BM	3000.54	3123.51	3.94
	SF	400.07	418.02	4.29

*Units for BM (kNM) and SF (kN)

Table 2: Manual calculation vs FEA: 28m span

Beam	Item*	Manual calc.	FEA	Diff. (%)
TM	BM	2347.52	2473.83	5.11
	SF	335.36	354.30	5.34
I20	BM	2344.15	2404.90	2.53
	SF	334.88	352.07	4.88
U12	BM	2613.81	2731.94	4.32
	SF	373.40	391.73	4.68

*Units for BM (kNM) and SF (kN)

Table 3: Manual calculation vs FEA: 24m span

Beam	Item*	Manual calc.	FEA	Diff. (%)
TM	BM	1724.71	1835.66	6.04
	SF	287.45	306.52	6.22
I20	BM	1722.23	1780.62	3.28
	SF	287.45	303.71	5.49
U12	BM	1920.35	2025.09	5.17
	SF	320.06	338.63	5.48

*Units for BM (kNM) and SF (kN)

Based on the comparison above, the differences are between 2.5-6.2%, thus, it has proven that the models carried out can be considered as acceptable. The FEA results were also validated further with F.Sahaya et al [5] and were found in good agreement.

Normally, different type of beam is chosen based on the span lengths of the bridge and its application. I-beam section is one of the most popular types implemented, as it has both flange at the bottom and top in order to cater more compressive and tensile forces. T-beam has no flange member at the bottom which then lack in terms of tensile forces. The web of these beams is used to cater shear stress as well as provide greater separation for the coupled forces of bending moment. On the other hand, U-Beam has void that helps to improve torsional stiffness of the beam. Note that, these beams having different shapes also means that they have different depth, width, area, centroid, second moment of area, section modulus and self-weight. And these will affect the beam behaviour.

According to Fig.8 to Fig.10, types of beam and span lengths have significant impact on the bending moment, shear force and deflection of the bridge deck analysis. Logically, the longer the span length of a bridge, the more load it must carry and of course the more tendency for it to be bended, sheared and deflected as illustrated in Fig. 8, Fig. 9 and Fig.10 respectively. Thus, bending moment, shear force and deflection increases as the span length increases.

Based on Fig.8, U12-beam has the highest maximum bending moment among the three type of beams, with values of 10586.006kNm, 9480.087kNm and 7258.018kNm for span length 30m, 28m and 24m respectively. Whereas, TM-beam has maximum bending moment value of 10291.522kNm, 9220.179kNm and 7066.969kNm for span length 30m, 28m and 24m respectively. Among the three beams, I20-beam has the lowest maximum bending moment value of 10105.610kNm, 8349.121kNm and 6561.723kNm for span length 30m, 28m and 24m respectively.

Similarly, for the shear force, based on Fig.9, U12-beam has the highest maximum shear force among the three type of beams, with values of 1276.682kN, 1255.682kN and 1174.735kN for span length 30m, 28m and 24m respectively. Whereas, TM-beam has maximum shear force value of 1230.95kN, 1212.709kN and 1140.113kN for span length 30m, 28m and 24m respectively. Among the three beams, I20-beam has the lowest maximum shear force value of 1217.216kN, 1209.759kN and 1134.851kN for span length 30m, 28m and 24m respectively.

Finally, Fig. 10, illustrated the maximum deflection for each beam with 3 different span length. Again, U12-beam has the highest value, but now for the deflection with values of 155.642mm, 124.317mm and 74.769mm for span length of 30m, 28m and 24m respectively. While for TM-beam, its maximum deflection values are 134.265mm, 107.388mm and 64.746mm for span length 30m, 28m and 24m respectively. The lowest maximum deflection is obtained from I20-beam with values of 111.137mm, 78.927mm and 47.433mm for span length 30m, 28m and 24m respectively.

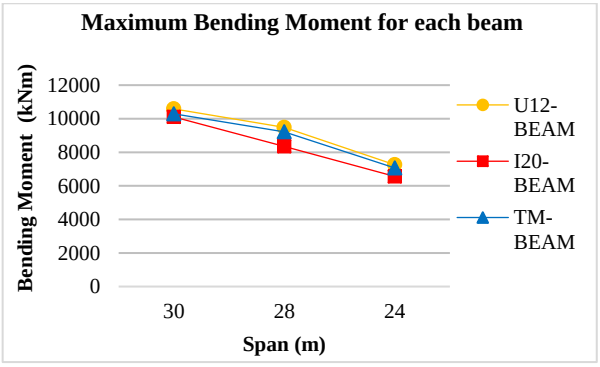

Fig.8: Maximum bending moment for each beam

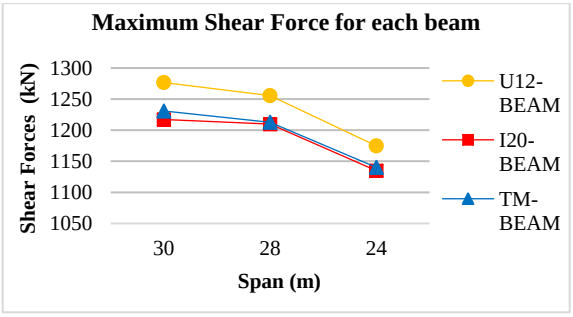

Fig.9: Maximum shear force for each beam

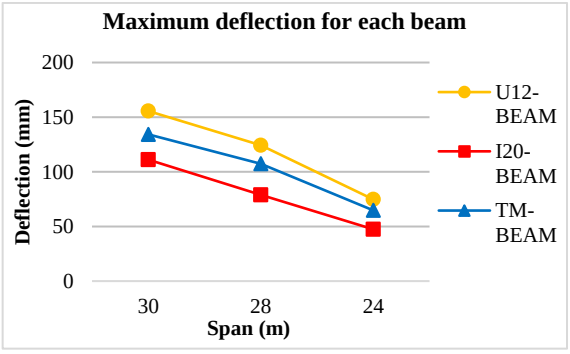

Fig.10: Maximum deflection for each beam

For the same span lengths and loads of the three beams types, I20-beam has the least value of maximum bending moment, shear force and deflection. And as expected, these values decrease as the span length decreases. Thus, I20-beam is strongly recommended. Note that, other factors should also be considered for the final decision, namely; ease of construction, the amount of reinforcements, formworks, concrete and tendon. Nevertheless, the design choices are in the hand of the engineer and the final decision will still be in the hand of the client.

CONCLUSIONS

Maximum bending moment, shear force and deflection were found from U12-beam, followed with TM-beam and I20-beam respectively Thus, it can be concluded that I20-beam is the best option as compared to TM-beam and U12-beam. Apart from the beam shape, the span length also affects the bridge deck analysis, as the longer the span length, the values of bending moment, shear force and deflection will also increase. Note that, other factors should also be considered for the final decision, namely; ease of construction, the amount of reinforcements, formworks, concrete and tendon. Nevertheless, the design choices are in the hand of the engineer and the final decision will still be in the hand of the client.

ABSTRACT

Waste activated sludge (WAS) obtained from a modified tapioca starch wastewater treatment plant has potential for use as feedstock for biogas production. However, it has a very low C/N ratio of 4.3, leading to a low methane yield. Co-digestion of WAS with starch sludge (SS) can potentially provide balanced nutrients and can enhance biogas production. The results from a biochemical methane potential (BMP) test showed that using WAS as a single feed stock provided a low biogas production at 80 L/kg TVS_{added}. In co-digestion, the addition of 30% and 50% SS increase the biogas yields by as much as 150 and 209 L/kg TVS_{added}, respectively. However, the addition of 70% SS reduces the biogas yield to as low as 117 L/kg TVS_{added}. The result also showed that the optimum condition for biogas production is achieved at 2% TVS_{added} of mixed WAS and SS (1:1) with a desired C/N ratio of 23.56. The increase in % TVS_{added} of the mixed feedstock resulted in a reduction of the biogas yield. The co-digestion of WAS and SS (1:1) also improved the rate of digestion and enhanced the system stability. TVS removal efficiency of the mixed WAS and SS was 41.44% higher than the efficiency when using WAS alone. Moreover, the result of continuous stirred tank reactor (CSTR) confirmed that the co-digestion ratio of WAS:SS (1:1) can enhance biogas yield and methane yield at 301 and 142 L/kg TVS_{added}, respectively at retention time of 11 days.

Keywords: Waste activated sludge, Starch sludge, Co-digestion, Biogas yield

INTRODUCTION

Modified tapioca starch is a value-added product. Thailand is the world's largest exporter of modified tapioca starch, it exported approximately 1.01 million tons with a value of 649 million dollars in 2017 [1]. The modified starch is produced from native tapioca starch that has been changed in its properties to provide the characteristics needed for specific uses. Two major sources of solid waste generation from the production process commonly consist of starch sludge (SS) from a primary sedimentation tank and excess waste activated sludge (WAS) from a secondary sedimentation tank. The reaction and drying starch processes are expressed as mostly a loss of SS. Generally, the tapioca starch loss rate discharges as large quantities, with wastewater comprising approximately 1 percent of raw starch [2]. SS was dewatered and sold at a low price of approximately 73-97 dollars per ton [3] to produce animal feeds that were not economically valuable.

Due to the large quantities and nutrients of WAS, many researchers have studied the biogas production potential from various sources of WAS. For example, Wang et al.[4] reported that the methane production from WAS of an oil refinery plant was 228 L/kg COD_{added}. Karlsson et al.[5] found that the WAS of six Swedish pulp and paper plants could produce methane in the range of 100-200 L/kg TVS_{added}, and Bolzonella et al. [6] found that WAS from four Italian wastewater treatment plants could produce methane between 500-900 L/kg TVS_{added}. WAS is a substrate with high potential for biogas generation. However, WAS has a very low C/N ratio that typically ranges from 6 to 9, thereby possibly limiting the efficiency of biogas production [7]. An excessive amount of nitrogen in the WAS can lead to an overabundance in ammonia accumulation and result in a subsequent inhibition to methanogenesis. [8].

The co-digestion with a rich carbon substrate may be an effective option for improving nutrient balances and biogas production. According to the co-digestion of 95% sewage sludge with 5% glycerol that is rich in carbon content, the biogas yield may be increased by almost 67.4% compared to the digestion of sewage sludge alone [9]. Moreover, co-digestions may offer several advantages such as an improved buffer capacity, an increased biodegradation of feedstock as well as dilutions of toxic substances, which will lead to increases in biogas yields [10].

Thus, it is more appropriate to use SS as a co-substrate with WAS. Meanwhile, this approach helps to tackle the limitation of the pH drop at the beginning of single SS digestion. Because WAS, consisting of 95 percent of bacterial cells [11], has a slower digestion rate than SS consisting of mostly carbohydrates.

This research aims to study the biogas production potential, system performance and TVS removal efficiency of different co-digestion ratios between WAS and SS using the biochemical methane potential method (BMP) for experimentation and the response surface methodology (RSM) for analysis.

MATERIALS AND METHODS

Feedstock and inoculum preparation

The WAS and SS were sampled from a primary sedimentation tank and a secondary sedimentation tank of an activated sludge wastewater treatment process of the modified tapioca starch factory in Rayong province, Thailand. The feedstocks were analysed for moisture, pH, total solids (TS), total volatile solids (TVS) and the carbon to nitrogen (C/N) ratio. Then, the WAS and SS were stored at 4°C before the experiment.

The feedstock was prepared at different ratios of WAS and SS. The %TVS of each substrate in the feedstock were calculated using the following Eq. (1):

$$TVS_1W_1 = TVS_2W_2 \quad (1)$$

Where:

TVS_1 = TVS of the feed substrate (% by wet weight);

W_1 = Weight of substrate (g);

TVS_2 = TVS of feedstock (% by wet weight); and

W_2 = Weight of feedstock (g).

The seed sludge from the up flow anaerobic sludge blanket (UASB) tank of the beverage factory in Pathum Thani province, Thailand was used as an inoculum in this experiment. The TVS of inoculum was prepared at 2.5%.

Experimental design

The co-digestion ratios of WAS with SS were established using Design Expert Software version 10 based on a central composite design (CCD) with an alpha value of 1.414. The TVS of each substrate was specified within the range of 0-2% in which the codes and scales of the variables are shown in Table 1. This experiment consisted of 13 runs, and each run was conducted in triplicate.

The experimental design of the variables was 13 runs with the biogas yield as the response value (Table 3). The proportions of each substrate were varied at 0, 30, 50, 70 and 100 percent while the C/N ratios were in the range from 6.06 to 56.44, which covered the optimum C/N ratio ranging between 20 and 30.

Table 1 The codes and scales of variables

Independent variable	Unit	Coded level				
		-1.414	-1	0	+1	+1.414
WAS concentrations	% TVS	0	0	1	2	2.414
SS concentrations		0	0	1	2	2.414

Biochemical methane potential (BMP) test

A biochemical methane potential (BMP) test was applied to assess the biogas production efficiency of the AD system based on the earlier suggestion of Owen et al. [12]. The ratio of feedstock to active inoculum of 60:40 (by volume) was added to 125 ml serum bottles with working volumes of 80 ml. The pH was initially adjusted using a digital pH meter in the range of 6.8-7.2 by adding sodium bicarbonate ($NaHCO_3$). The headspace of the prepared serum bottles was purged with nitrogen gas before being sealed with airtight rubber stoppers and covered by an aluminium cap. Then, they were incubated on a rotary shaker at a room temperature of 25-30°C with a speed of 140 rpm for 45 days. The volume of biogas was monitored daily using a syringe. The produced biogas was measured by reading the scale on the syringe (Fig. 1).

(A) (B)

Fig. 1 BMP test (A) BMP bottle incubated on the shaker and (B) biogas measurement

Continuous stirred tank reactor (CSTR) test

The optimum co-digestion ratio of WAS:SS obtained from the BMP test was used for further batch CSTR test. The ratio of inoculum to feedstock was 40:60 by volume. The CSTR working volume was 5 L and mixed with a speed of 70 rpm. The entire pH of the mixture between 6.8 and 7.2 by adding sodium bicarbonate ($NaHCO_3$). The biogas volume was measured by a gas counter based on a water-gas displacement system connected to a sensor counter (Fig. 2). The CH_4 content in biogas was analysed by GC (Model Shimadzu GC-2014, Shimadzu Corp., Japan).

Fig.2 CSTR reactor and gas counter

Calculations and statistical analysis

The biogas yield (L/kg TVS_{added}) after 45 days of incubation was calculated using the following Eq. (2):

$$\text{Biogas yield} = BV/TVS_{added} \quad (2)$$

Where:

BV = Cumulative biogas volume (L); and

TVS_{added} = Weight of TVS of feedstock added to the bottle (kg).

An R squared (R^2) analysis was applied to evaluate the RSM model's appropriateness. The optimum co-digestion ratios can be obtained by considering a three-dimensional RSM plot of biogas yields, the system performance and the TVS removal efficiency.

The pH, volatile fatty acids (VFA), alkalinity (ALK) and TVS of the effluent were analysed. All analytical methods were performed by following the American Public Health Association (2017) standard method for the examination of water and wastewater.

RESULTS AND DISCUSSION

The characteristics of the feedstock

The characteristics of the feedstock and inoculum are presented in Table 2. The WAS collected from the secondary sedimentation tank contained a low total solids content at 7.56% by wet weight. Since the major composition is an aerobic bacterial cell, it has a high TVS/TS ratio at 0.78 that was suitable for an anaerobic digestion (AD) system. The pH of WAS was 6.5, and the C/N ratio was 4.3, which can lead to a low biogas yield. Therefore, the digestion of WAS alone may not suitable for biogas production. Thus, such waste may have a substantial advantage on the nutrient balance when co-digested with SS.

The SS from the primary sedimentation tank consisted of the residual starch in the acidic slurry, at a low pH of 4.48. Generally, tapioca starch contains a large amount of amylopectin at up to 83%, which is easy to digest [13]. Additionally, the high C/N ratio of 242 may lead to VFA accumulation and an important drop in pH. Both its pH property and VFA accumulation have a similar adverse effect on the system pH drop, which consequently inhibits methanogenic activity. Concern about this limitation was an important reason for why the AD of SS alone was not appropriate. The useful application of SS was co-substrate with WAS that may help to solve the prior problem by balancing the nutrients and enhancing the biogas yield higher than using WAS alone.

Table 2 Characteristics of co-digestion feedstock and inoculum

Parameter	WAS	SS	Inoculum
Moisture (%)	92.44±1.01	39.09±0.62	93.05±0.14
pH	6.50±0.03	4.48±0.01	-
TS (% by wet weight)	7.56±1.01	61.00±0.45	6.95±0.14
TVS (% by wet weight)	5.92±0.04	31.26±0.03	6.73±0.03
C/N ratio	4.3	242	8.51
TVS/TS	0.78	0.51	0.97

Note: n = 3

Effect of the initial feedstock concentration on the digestion time

Fig. 3 showed the cumulative biogas yield from the WAS and SS feedstocks at various concentrations of TVS_{added}. The digestion time was affected by source of feedstock for both WAS and SS (as a single digestion or co-digestion system). When using WAS as a single substrate, the biogas yield was highest at a reaction time of 38 days, while when using SS as a single substrate the reaction time was 45 days at 1% TVS. Various co-digestions of WAS and SS may reduce the digestion time to less than 30 days. The co-digestion of WAS:SS at a ratio of 1:1 and 2% TVS_{added} achieved the shortest digestion time of 25 days. At this condition, the biogas yield was 209 L/kg TVS_{added}. We emphasize that SS has high potential for co-digestion with WAS.

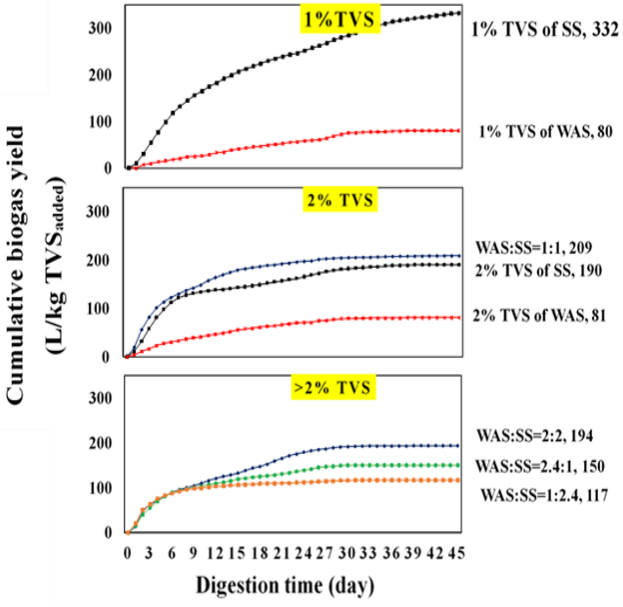

Fig. 3 The cumulative biogas yields from different feedstock and TVS concentrations

Effect of the co-digestion ratio on biogas yields

A three-dimensional plot (Fig. 4) was developed by relating the WAS and SS concentrations to the biogas yields by using RSM analysis. The determination coefficient (R^2) was 0.9561, which indicated that the model is highly capable of explaining up to 95.61% of the experimental condition. The result showed that the major factors impacting biogas yield were the ratios of WAS and SS and the initial concentrations of TVS_{added}. The biogas yield increase with the SS ratio is shown in Fig. 4. At 1% TVS_{added}, the highest predicted biogas yield may be achieved at 301 L/kg TVS_{added} by using SS alone, while the lowest predicted biogas yield occurred at 80 L/kg TVS_{added} by using WAS alone (Table 3). Many studies reviewed that the methane yield from WAS varied in the range of 100-900 L/kg TVS_{added} depending on the source of feedstock, such as: 100-200 L/kg TVS_{added} from pulp and paper plants [5], 500-900 L/kg TVS_{added} from a municipal wastewater treatment plant in Italy [6], 183-200 L/kg TVS_{added} from a municipal wastewater treatment plant in China [14] and 190 L/kg TVS_{added} a municipal wastewater treatment plant in France [15].

The co-digestion of WAS: SS at ratio 1:1 is able to achieve the highest predicted biogas yield at 210 L/kg TVS_{added}. The co-digestion of WAS and SS (1:1) enhanced the biogas yield by 159% compared to the WAS alone (2:0). Meanwhile, the biogas yield from using SS as a single feedstock at 2%TVS_{added} (0:2) was 10% lower than using a mixed feedstock (1:1). Thus, the co-digestion of the WAS:SS at a ratio of 1:1 is suitable for usage at 2% TVS_{added}.

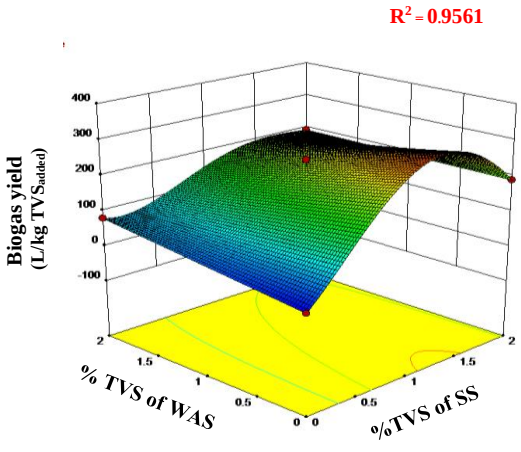

Fig. 4 The RSM pot of the influences of WAS and SS concentrations on the predicted biogas yields

Effect of the C/N ratio on biogas yields

Table 3 showed the C/N ratios of biogas feedstock and biogas yields in each CCD experimental run. The result showed that the C/N ratio of the initial feedstock influenced the biogas yield. The optimum C/N ratio was in the range of 20-30 [16]. The results showed that the optimum biogas yield depended on the ratio of WAS and SS that resulted in a suitable C/N ratio for methanogens. The addition of the SS to WAS feedstock resulted in the increase of the C/N ratio, which may thus increase the biogas yield. For example, the mixed feedstock of WAS and SS at a ratio of 1:1 and the C/N ratio of 23.56 and 29.30 (2% and 4% TVS, respectively) may achieve a biogas yield as high as 209 and 194 L/kg TVS_{added}, respectively. However, the addition of SS to WAS at a higher ratio than 1:2.4 would reduce the biogas yield since the C/N ratio was 43.57, which exceeds the optimum range.

In the case of using SS alone at 1% TVS_{added}, the highest biogas yield was achieved 332 L/kg TVS_{added}. This is because during the preparation of feedstock, seed was added to the SS feedstock (40:60) before the BMP test. Thus, the C/N ratio of using SS alone was 35.2. Meanwhile, the C/N ratio of 2% TVS of SS alone was 56.44.

Table 3 C/N ratio of the biogas feedstock and biogas yield in each CCD experimental run.

Run	TVS concentration (% by wet weight)		Proportion (%)		C/N ratio	Biogas yield (L/kg TVS_{added})	
	WAS	SS	WAS	SS		Actual value	Predicted value
1	0	0	0	0	8.51	0	0
2	1	0	100	0	6.79	80±0.42	80
3	2	0	100	0	6.06	81±16.62	81
4	2.41	1	70	30	16.86	150±5.56	119.43
5-9	1	1	50	50	23.56	209±25.55	210.42
10	2	2	50	50	29.30	194±8.42	193.92
11	1	2.41	30	70	43.57	117±3.23	116.8
12	0	1	0	100	35.21	332±3.57	301.41
13	0	2	0	100	56.44	190±13.08	189.88

Performance of AD

Fig. 5C showed the pH and the ratios of VFA and ALK of each experimental run after 45 days of operation. At the beginning of the experiment, all reactors were adjusted so that the pH of the reactor was in range in 6.8-7.2 with $NaHCO_3$. The reactors using WAS alone and the co-digestion of the WAS:SS ratio were 2.4:1 and 1:1 (run 2-9), while the final pH values were in the range of 7.01-7.27 (Fig. 5B). VFA/ALK ratios of these reactors were in the range of 0.09-0.23. These values may be an indicator that the reactors were working within the optimum interval for methane formation, which should be lower than 0.4 [17]. This may be because WAS had the low concentrations of readily available organic carbon [14]. Typically, it is not quickly degraded to VFA by the hydrolysis, acidogenesis and acetogenesis stages. Therefore, the VFA produced in the co-digestion ratios of 2.4:1 and 1:1 can be converted into biogas through the methanogenesis stage with a suitable conversion rate that resulted in

no excess VFA accumulation occurring. This result was confirmed by the neutral pH value and the lower VFA/ALK ratio in this digestion system.

For reactors using SS alone and the co-digestion of the WAS:SS ratio of 1:2.41 (run 11-13), the pH values were in the range of 4.16-6.86, while VFA/ALK ratios were in the range of 2.55-15.8. The co-digestion that added the high ratio of SS had the low biogas yields. The SS is too much starch content, causing the speed of the VFA production in the early stage to be faster than the speed of VFA consumption by methanogenic bacteria, which resulted in a high VFA accumulation. This dynamic may inhibit the methanogenesis process [18]. These results are in line with those obtained by Cuzin et al. [19], who reported that the AD of cassava peels consists of a major biodegradable starch that usually results in excess acid production, which affects the pH drop and is highly toxic to methanogens. Anunputtikul and Rodtong [20] showed that there was the decrease in pH in the initial fermentation of rich starch cassava tubers.

Meanwhile, the co-digestion of WAS:SS at the ratio of 1:1 may give the highest biogas yield compared with other co-digestion ratios. Additionally, it can enhance the performance and system stability with a lower VFA/ALK ratio of 0.23 and a neutral pH of 7.01 compared to the digestion of SS alone. Thus, selecting the optimum co-digestion ratio should also consider the biogas yield, the system stability and the TVS removal efficiency.

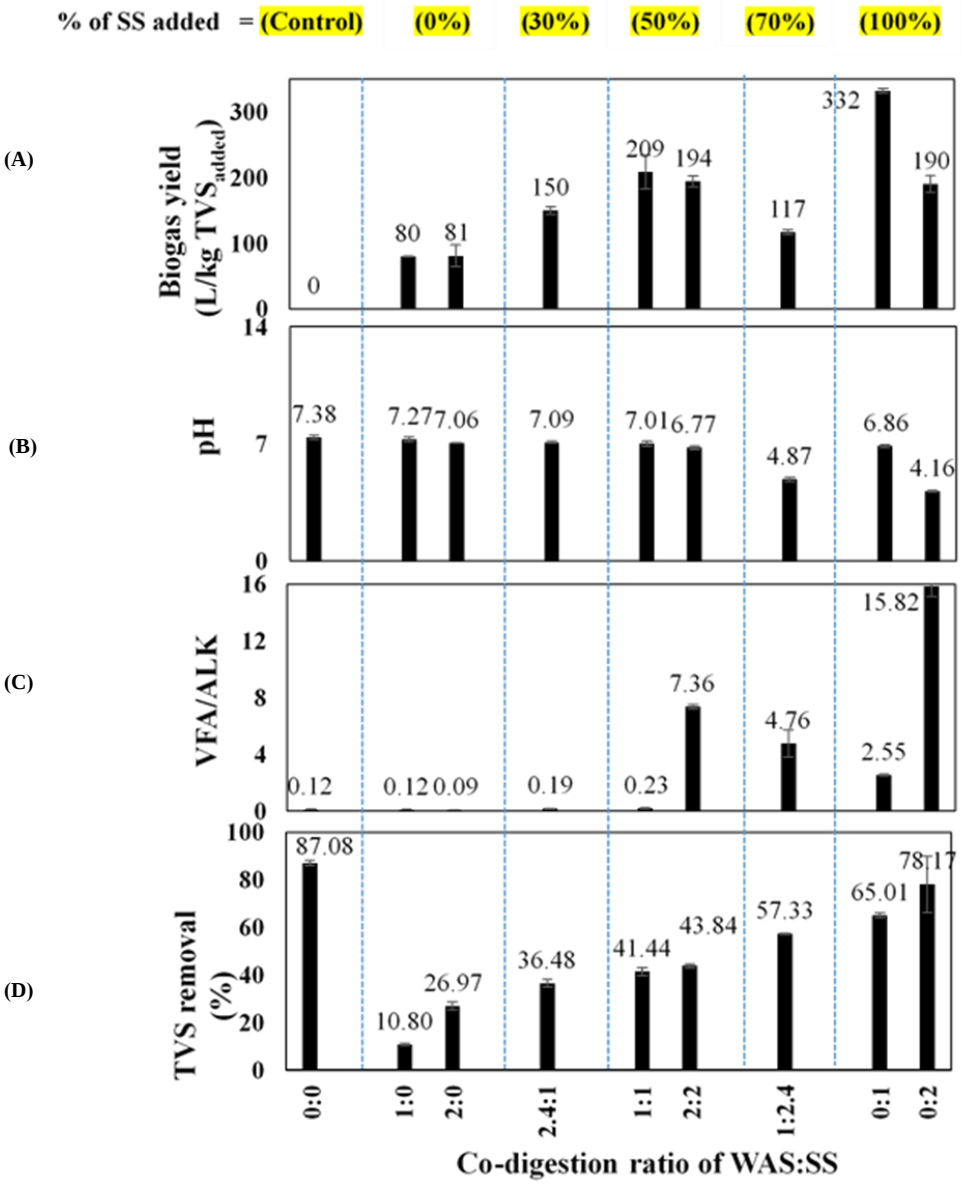

Fig. 5 The performance and system stability in the co-digestion of WAS:SS (A) Biogas yield, (B) pH, (C) VFA/ALK ratio and (D) TVS removal

TVS removal efficiency

Increasing the ratios of the added SS (at the co-digestion of WAS:SS ratios of 1:0, 1:1 and 1:2.4) resulted in significant increases in the TVS removal efficiency of 10.80%, 41.44% and 57.33%, respectively (Fig. 5D). Since WAS consists of a combination of microorganisms, approximately 95% of bacteria and 5 percent of higher organisms [11], it is more difficult to digest than SS [14]. Thus, increasing the TVS removal efficiencies depends mostly on the SS, which is easy to digest. Specifically, at the co-digestion ratio of 1:1 (WAS:SS), the TVS removal efficiency was 41.44% higher than it was when using WAS alone, which achieved an efficiency of 10.80%. Thus, this result verified that the co-digestion ratio of 1:1 may be a promising and practical option for the use of WAS and SS as feedstock in the anaerobic digestion process due to improved TVS removal efficiency, high biogas yield and proper system stability.

CSTR test

Fig.6 showed that the biogas yield at the co-digestion of WAS and SS (1:1) in the CSTR was 301 L/kg TVS_{added} at retention time of 11 days. Since the CSTR digestion was carried out with complete mixing, so the biogas yield was higher than those obtained from BMP test. Moreover the reaction time was also faster than BMP test. Considering the methane (CH_4) yield and content equal to 142 L/kg TVS_{added} and 47%, respectively. The final pH and VFA/Alk ratio was equal to 7.04 and 0.36, respectively. It was emphasis that the system has good performance.

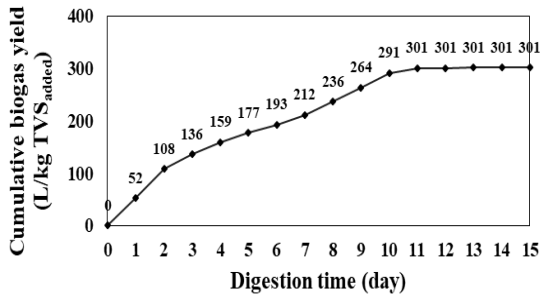

Fig. 6 The biogas yield in the CSTR

CONCLUSIONS

WAS and SS may be used as feedstocks for biogas generation. The optimum condition for biogas production was the co-digestion of WAS:SS at the ratio 1:1 at 2% TVS_{added}. At this condition, biogas yields may be achieved at 209 L/kg $TVS_{added.}$ Result from CSTR batch experiment of such condition showed that biogas yield and methane yield were high as 301 and 142 L/kg TVS_{added}, respectively. After operation for 11 days, the pH and VFA/ALK ratio was7.04 and 0.36, respectively. The biogas obtained in this anaerobic digestion can be used as an alternative fuel in a hot air generator for the starch drying process. Moreover, there are cost-saving for WAS sent to landfills and environmental advantages in reducing the greenhouse gas emissions from landfills.

HEAVY METAL SEDIMENT AVAILABILITY ASSESSMENT OF THE REMOTE CONTAMINATED UPSTREAM OF THE MAE TAO BASIN

Khunin. T. [1], Wongyai s.[2] Somprasong K.[3]
[1,2,3] Department of Mining and Engineering, Faculty of Engineering,
Chiang Mai University, Thailand

ABSTRACT

The Mae Tao Basin in Mae Sot district, Thailand, was a large remote cadmium contaminated area. This area has been reclaimed after the closing of two zinc mine in 2016. Even supposing that the contamination of cadmium in this area is related to the mine operation, but the investigation of other heavy metal in the upstream area has not been completely established. In this study, the Portable X-ray Fluorescence Spectroscopy (P-XRF) were assigned as the analysis tool for retrieving the primary concentration levels of heavy metals. Since the upstream area of the Mae Tao Basin is a remote area, covered with deciduous forest, therefore must collect samples for analysis. The recorded concentrations of heavy metals were analyzed and transformed into data input in form of raster calculation layers. These layers were combined with Revised Universal Soil Loss Equation (RUSLE) incorporated with geographic information system (GIS) with the intention of estimating the heavy metal sediment availability. The study's result the discovered heavy metals, other than cadmium, are arsenic (As), manganese (Mn), lead (Pb), zinc (Zn) and mercury (Hg). Additionally, the concentration of arsenic revealed by the investigation is ranged from 6.104 – 297.122 mg/kg while its highest sediment availability is equal to 38.36 g/m 2 /y. This contamination level is exceeding the acceptable level for arsenic in soil of Thai at 3.9. According to study's result, the further investigation on arsenic in the upstream area of the basin is strongly recommended to be conducted.
Keywords: Erosion, GIS, Contamination, Sediment, RUSLE

INTRODUCTION

The Mae Tao Basin covers 6090.75 ha (59.61 km^2). The basin contains four significant land utilizations which are mining production areas, corn field, rice paddy fields, and deciduous forest areas. This area has been considered to be Thailand's largest zinc deposit, is in Mae Sot district, Tak province as can be followed in Fig1. It is a remote area where the contamination of cadmium has been continuously reported. [1] According to the existence of cadmium which naturally born in association with the occurrence of zinc- composite mineral, so the contamination was widely detected over the area, especially in the main water resource, named as the Mae Tao Creeks.

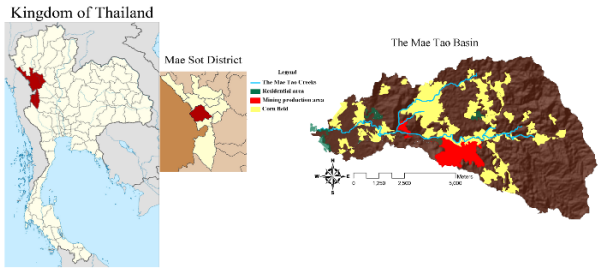

Fig1. Location of the Mae Tao Basin

While cadmium has been considered to be the main contaminants, degrading the qualities of the environmental phases of this area, thus the study of the availability of other heavy metals has not been archived especially in the upstream area of the basin.

Rainfall erosion was found to be one of the major mechanics that make cadmium available for spreading throughout the basin [2]. In order to illustrate this circumstance as a spatial model, the Revised Universal Soil Loss Equation (RUSLE) has been applied to evaluated possible amount of the surface erosion. Application of RUSLE is accustomed to the remote sensing for land surveying and development.

The integration between geographic information system (GIS) technology and this erosion models has been proven to be effective at estimating the magnitude and distribution of erosion. It has been effectively applied in the monitoring of contaminated area. [3] successfully applied RUSLE as a main tool in the identification of heavy metals distribution patterns and the likely sources of pollution in the Songkhla Lake Basin, southern Thailand.

Recently, X-ray fluorescence analysis has been developed into portable analytical device and emerged as a very powerful technique for in-situ elemental analysis of environmental samples [3]. The Portable X-ray fluorescence spectroscopy (PXRF) , demonstrated in Fig.2, offers non-destructive analysis of both quality and quantity of the mineral composition in multi-element samples. This instrument provides a competence in conducting a reliable on filed-chemical analysis with a short period of time.

Figure 2. Portable X-ray fluorescence spectroscopy (PXRF)

The application of PXRF in the environmental and mining sector to determine elemental distributions and quantifying element contents were found to be reasonable. It can generate reliable, high quality elemental concentration data for metal-contaminated soils [4].

By combining the concentration profiles of the area, analyzed directly PXRF with the results from RUSLE, the potential migration fluxes of the heavy metals, including Arsenic (As), Lead (Pb), and Mercury (Hg), the sediment availability of these contaminants in the upstream of these study area can be illustrated.

METHODOLOGY

The overall framework of the study is established in Fig.3

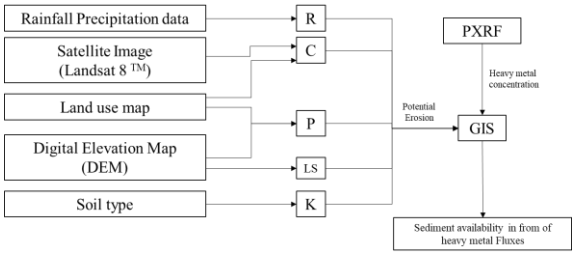

Fig.3 Framework of the study

Rainfall precipitation data were attained by Thai Meteorological Department (TMD). The soil classification and land use maps were acquired from the Land Development Department of Thailand (LDD). The Digital Elevation Map (DEM) of the study area was afforded by the Royal Thai Survey Department (RTSD). The satellite image of the basin, covering the study period were supported by GISTDA.

The data sets were separately analyzed in the purpose of preparing the required data input of RUSLE using GIS application. The potential erosion results were estimated in association with the concentration profile, gathered from the on-site analysis, using PXRF for establishing the potential heavy metal flux from erosion that occurred over the upstream of the Mae Tao Basin Area.

Heavy metal concentration analysis.

The upstream area of the Mae Tao Basin, is classified as a remote area, where the hauling of sampling out of the area for chemical analysis is merely possible. Accordingly,PXRF, capable for on-site analysis, then applied as analytical instrument. Since the standard method for PXRF has not been release, the analysis on heavy metal content in the soil surface of the area were conducted following ASTM E 1626 – 13 [5] at the sample preparation state. Soil samples with a depth of 30 cm were analyzed to determine contents of heavy metal including Arsenic (As), Lead (Pb), and Mercury (Hg). Fifty two samples, cover the reachable area in the upstream of the basin,were colected and analyzed into the concetration profile,using GIS application.

Revised universal Soil Loss Equation.

Soil loss or soil erosion refers to the amount of soil moved from one particular area to another. This phenomenon were based on the relationship between raindrops, runoff and the erodibility of a certain area. RUSLE can give a quantifiable results of the erosion amout by extending the terms of cover management and support practices into the equation.

Cadmium contaminats in the basin adsorb with the overland sediment as residue from surface runoff, so the applying of RUSLE to illustrate the potential erosion of the area can reflect the possibility of the cadmium that can be release into the environmental phases. The Revised Universal Soil Loss Equation is presented in (1)

$$A = R \times K \times LS \times C \times P \qquad (1)$$

The R factor is the erosivity by rainfall runoff at a location. The K factor refers to the specific value of the inherent erodibility of the soil surface material at a specific area. The LS reflects the effects of topography, specifically a hill's slope, length, and steepness, on the rates of soil loss at a site.

The C factor expresses the effects of surface cover and roughness from the biomass to the rate of soil loss, while the P factor represents effects of soil conservation practices such as buffer strips for cover vegetation [3].

Parameter Determination

R factor

R factor calculations were conducted base on the study of [6] as can be seen in (2).

$$R = 0.4669X - 12.1415 \qquad (2)$$

K factor

The land use and soil classification map of the Mae Tao Basin are afforded from LDD in association with the study 's result of [2].

C factor

The familiar spatial estimation method for C factor is to assign values into land cover classes using classified remotely sensed images. Basically, the classification using NDVI analysis presents a high correlation with ecological variables as leaf-area-index, total vegetation cover or above ground biomass [7]

The C factor assigned in this study were based on the study of which were derived from the NDVI analysis result of the satellite images. According to [2], the method performs high accuracy when applied the calculation to the South-East Asia's NDVI analysis. The calculations were performed following (3) to (4)

$$NDVI = (NIR - R)/(NIR + R) \qquad \textbf{(3)}$$

$$C = 0.6 - 0.77NDVI \qquad \textbf{(4)}$$

Where NIR and R indicate channel or band of Landsat which are near infrared and visible red respectively.

P factor

The support practice factors (P) were assigned, according to [8] as a combination between slope data from the spatial analysis of DEM and land use map based on the criteria, prescribed in Table 1.

Table1 P factor assigned in this study

Land cover	P factor
Agricultural Area with Slope ≤ 8 %	**0.5**
Agricultural Area with Slope between ≥ 8 % and 20 %	**0.75**
Agricultural Area with Slope ≥ 20 %	**0.9**
Shrub, Secondary Forest and Forested Area	**0.1**

LS factor

LS-factor calculation was operated under the remote estimation technique using GIS application, following the equation of which is presented in (5). The calculation of LS factor for the surface area of The Mae Tao Basin is presented in Fig 4.

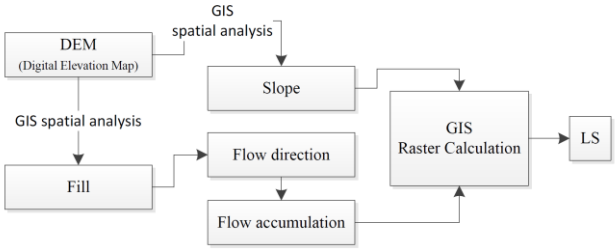

Fig.4 LS factor determination process

$$LS = \left(\frac{Flowacc \times resolution}{22.13}\right)^{m} (65.41\sin^2\theta + 4.56\sin\theta + 0.0654) \qquad (5)$$

The LS-factor refers to the surface terrain of the basin, affect by the slope gradient of in the form of percent gradient [9,10]. The slope gradient of the study area was calculated and analyzed based on spatial analysis technique [10]. The value of m, referred to a coefficient related to the ratio of rill to inter-rill erosion, was varied from 0.2 to 0.5, depending on the slope gradient and m, defined previously, was equivalent to 0.5 for slope > 5 %, 0.4 for slope between 3 %s to5 %, 0.3 for slope range pf 1 % to 3 %, and 0.2 for under 1 % slope.

In a purpose of calculating the flow accumulation, a DEM (30 m resolution) of the basin from the Royal Thai Survey Department (RTSD) was obtained and analyzed under the fill spatial analysis technique to avoid any discontinuity in the flow simulation which can be existed when water is trapped by cells of higher elevation. After that, the flow direction was generated from these filled grids. Flow accumulation was calculated based on the direction acquired from the flow direction analysis. As a final process, the raster calculation was applied to determine the LS-factor.

Potential heavy metal flux from erosion estimation

Potential erosion estimation. The calculation for potential erosion of the Mae Tao Basin was operated under the spatial analysis for raster calculation in GIS application, based on (1).

The potential erosion, obtained from RUSLE's estimation were combined with the heavy metal profile, using (6), to illustrate the sediment contaminated by heavy metal in the study area. In this equation, P_E is the potential availability of cadmium, while [H] stands for the heavy metal's concentration of the monitoring area.

$$P_E = [H]A \qquad (6)$$

RESULTS AND DISCUSSIONS

Potential erosion of the Mae Tao Basin

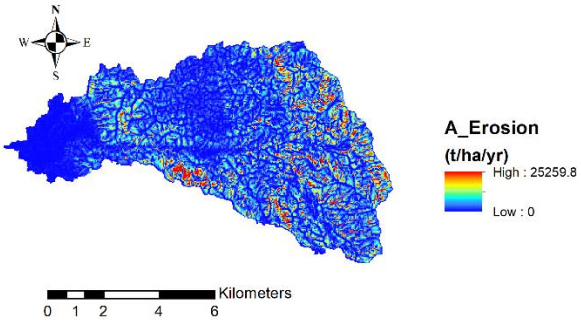

Fig.5 Potential cadmium flux from erosion of the basin

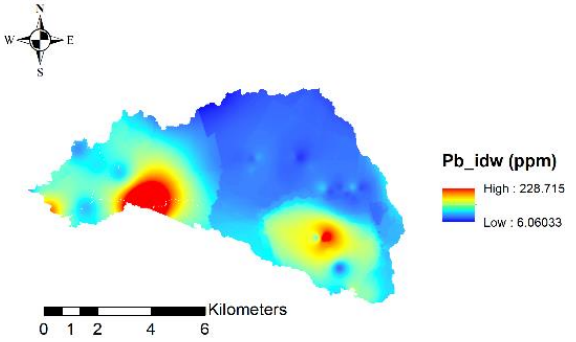
Figure 5 illustrates the potential erosion of the Mae Tao Basin in 2018. The potential erosion can be defined in form of raster map. High potential erosion was significantly detected in the mining production area and the upstream of the basin. The results also designate some other areas with high potential due to high soil erosion capabilities. The highest value of potential was found to be 25259.8 t/ha/y.

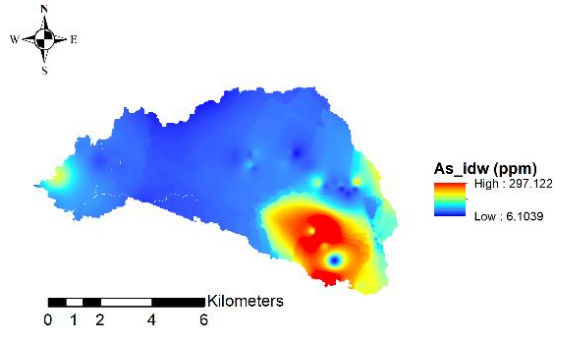
Heavy metal concentration's profile

As previously stated, the concentration of each contaminants was analyzed by PXRF and then transformed into raster-calculation layers. The analytical results indicated that high level of heavy metals can be notified in some parts of the basin as can be seen in Fig.6 to Fig.8.

Pb, As and Hg, considered to be lethal hazardous substances that can cause both long term and short-term diseases, were diffusely sensed all over the area of the basin as can be followed in Fig.6 to Fig.8.



(a)



(b)

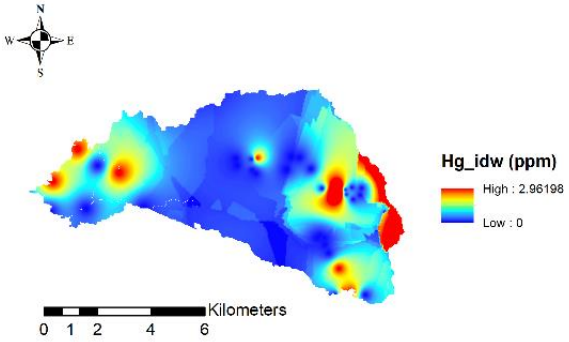


Fig.6 Heavy metal concentration profile (a) Pb, (b) As (c) Hg

Table 2 Comparison between heavy metal contents from the analysis and existed standards.

Heavy Metals	Concentration (ppm)				
	Max	Avg.	Min	SD	Standard in soil
Pb	228.175	36.98	9.27	1.62	400.00
As	297.122	44.88	6.00	0.59	3.90
Hg	2.961	0.53	< 0.02	0.13	23.0

In accordance with Table 2, Arsenic, mostly found in the agricultural area of the basin's upstream range from 6.00 to 297.122 ± 4.78 ppm were exceed the acceptable standards of Thailand [PCD] at 3.9 ppm. The concentration level of Pb and Hg is under the acceptable standard at 400 ppm and 23 ppm respectively. Pb's content, detected during the monitoring period were ranged from 9.27 to 228.175 ± 1.62 ppm, while Hg's concentration was ranged from 0.02 to 2.961± 0.13 ppm respectively.

Estimation result of potential cadmium flux from erosion

Consistent with Eq.6, the potential heavy metal fluxes from can be defined in form of raster map as established in Fig.7 and Table3.

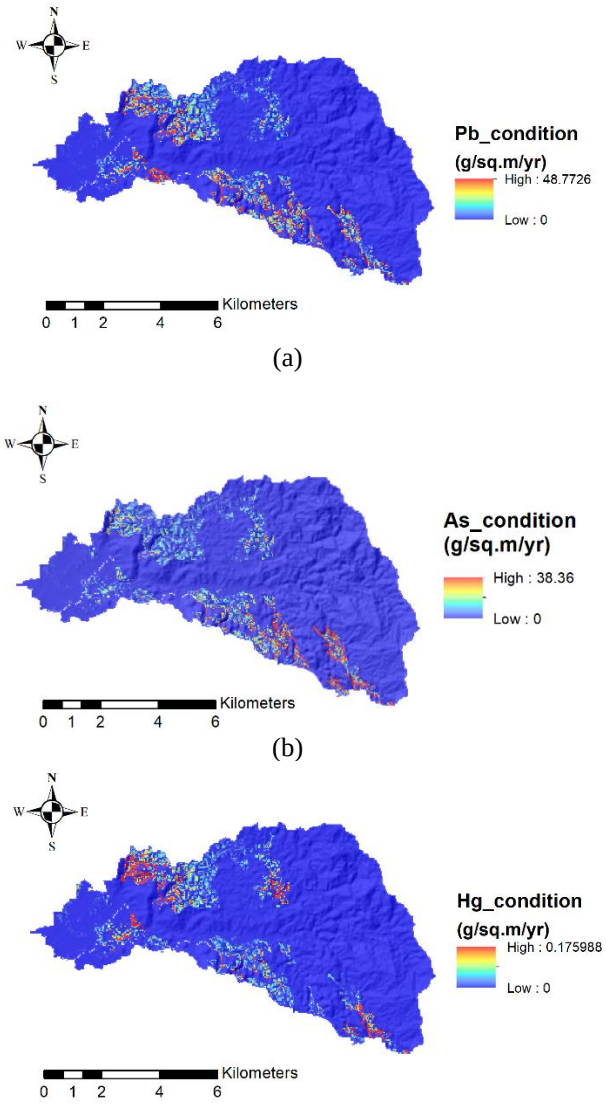

Fig.7 Potential heavy metal fluxes from erosion ($g/m^2/y$) (a) Pb (b) As (c) Hg

Table 3. Estimation results of potential cadmium flux from erosion

Heavy metals	Potential heavy metal fluxes from erosion ($g/m^2/y$)			
	Max	Min	Avg	SD
Pb	48.770	0.000	0.210	1.010
As	38.360	0.000	0.730	1.040
Hg	0.176	0.000	0.001	0.005

Along with the spatial analysis' results, the high potential flux value was perceived in the upper stream of the and some other areas, containing high soil erosion capabilities.

High level of the potential lead flux from erosion was compactly located in the downstream of the basin, as well as mercury. Lead discovered in the study area, contained potential migration availability at 0 to 48.77 ±1.01 $g/m^2/y$, while mercury contained 0.176±1.01 $g/m^2/y$ is mercury availability. The highest value of potential arsenic fluxes from erosion was found in the agricultural region in the upstream area at 38.36 ± 1.04 t/ha/y. The location where high availability of arsenic was densely sense was in the south-eastern upstream area of the basin.

Discussion & suggestion

Despite the fact that the Mae Tao basin has been contaminated by cadmium, but the degradation of environmental phases, caused by other heavy metals must be concerned. Arsenic, possesses abilities in causing both acute and chronic effect to the residents in the contaminated area such as hyperkeratosis, leading to skin cancer, were the most deleterious substance that need further remediation. There are two possible sources of arsenic in this study area. Firstly, the geological characteristic of the basin which is considered to be secondary deposition area of zinc and other metal compositions so that the high content of arsenic and other heavy metal contaminants can be sensed.

Likewise, the dense contaminated area with high potential erosion is the also classified as the agricultural area in which corn field are planted and vegetated. According to this circumstance, the contamination of heavy metal especially arsenic can be the results from fertilizers' utilization and irrigation.

Since the distribution process of arsenic can be different from cadmium, the monitoring on fate and transport of the contaminant must be conduct in a purpose of establishing a recommendation on the remediation procedure. Parts of the corn plant, including tassel, leaf, stalk, root and corn fruit sample should be separately analyzed to determine the accumulated arsenic content.

Mercury and lead, compactly sense in the downstream area of the basin, contains low level of potential flux during the rainfall incident. According to the heavy metal content and the detected location, the migration availability of these two contaminants is insignificant, compared to the exposing of arsenic, however long-time monitoring on the accumulation of them into forage plants must be considered.

As a suggestion to improve the quality of the estimation, the statistical analysis of the study's results should be accomplished in order to examine the accuracy and the precision of the results. Extended field observation for other input data should be concerned so that the estimation will be more fitted to the real incident occur in the study area.

CONCLUSIONS

The contaminant flux from erosion in the upstream area of the Mae tao basincan be estimated, based on RUSLE. It can illustrate the significant potential area which have a capability in releasing heavy metal attaching in form of the residue in the rainfall runoff. This integrated spatial techniques can effectually map out the potential sources of contamination especially in the remote area. This study has shown the capability of customizing this integrated method to characterize a remote heavy metal contaminated area.

The combination between the effects of low erosion resistance and being situated in a mountainous area results in high potential in releasing cadmium during the erosion incident.

For arsenic contamination, discovered in this case, further study of potential sources of the contaminant and its fate and transport must be accomplished in order to establish the suitable remediation and protection scheme

The further study and development in utilizing more precise parameter for soil erosion estimation will enhance the estimation efficiency of this integrate method and can be applied to another similar contaminated site.

DIFFERENCE OF FLOODING PHENOMENON WITH BANK BREACH BY DIFFERENCE OF BACK WATER EFFECT IN 2016 FLOOD AT TOKORO RIVER

Sho Adam Fukazawa[1], Yasuharu Watanabe[2] Tomonori Shimada[3]
[1,2]Kitami Institute of Technology, Japan, [3] Civil Engineering Reserch Institute for Cold Region

ABSTRACT

In recent years, bank breaching has occurred with high frequency. In August 2016, the eastern part of Hokkaido, Japan was hit by a heavy rainfall and the tributaries of Tokoro River (Sibayamsawa River and Toua River) had a bank breach caused by the back water of Tokoro River. Although both tributaries were almost identical in size and both junctions were very close, the situation of inundation significantly differed. At the breaching point of the Sibayamasawa River, the inundation flowed toward the upstream side of the inland, while at the Toua River it was perpendicular to the channel.

In order to understand the cause of the difference in phenomena, the reproduction of the breaching situations of both rivers at tributaries were attempted using the numerical simulation model "iRIC Nays 2D Breach".

Keywords: Four or five keywords (First characters of each keyword are in uppercase letters), Italic

1. INTRODUCTION

In recent years, heavy rainfall has occurred highly frequently due to the effects of climate change, and many cases of damages cause through bank breaches in small and medium-sized rivers and tributaries of large rivers have been reported. In August 2018, the torrential rain experienced in the western part of Japan lead to a total of five separate bank breakages at three tributaries of Odagawa River in the area of Mabicho[1], Kurashiki City's. Also in August 2016, while the heavy rainfall caused various disasterous situations as a result of bank breaches and river flow fluctuations in many parts of Hokkaido, in Tokoro River many disastrous cases such as bank breach, bank erosion sand blast, etc. were reported. Under such circumstances as this, a bank breach with inundation occurred seemingly as a result of the back water phenomenon arisen in the tributaries Tokoro River (Sibayamasawa River and Toua River). The Figure 1 shows the location of the main stream of Tokoro River and the tributaries of Sibyamasawa River and Toua River. Although both tributaries were almost identical in size and both junctions were very closely located, the situation of inundated were largely differed. Toua River's bank breach phenomenon occurred 300m away from the bank position and the scour scars which was formed by the inundation flow streched perpendicularly to the river channel. In contrast, the Sibayamasawa River's bank breach phenomenon made the scour scars that the embankment ground been formed by inundated flow more toward the upstream side of the inland. The width of scour scars was wider than Toua River, but the length was shorter than Toua River. In fact, it was half length of Toua River, extending only for a length of 150m from the bank. Although there are examples illustrating the phenomenon of bank breach widening had the examples of bank breach including a scale model[2] made with a bank breach experiment[6] using a full size model of water channel and numerical calculation of bank breach widening performed by Shimada[5] and Tujimoto[4]. they were all for self-flowing sections and the process of bank breach widening in the case of bank breach occurring in the section of back water channel isn't clear yet. It will be an important piece of information for the reduction of natural disaster occurring at the time of bank breach, if how bank breach widening progresses is clarified not only at the self-flowing section but also at the section of back water. In this research an analysis was carried out to understand the cause of difference in phenomena between the two tributaries of Sibayamasawa River and Toua River. As the impression after the bank breach was grasped by field survey, but the phenomenon during bank breach was not confirmed, the numerical simulation software model called "iRIC Nyas 2D Breach"[6] was used to confirm the bank breach widening phenomenon.

2. OUTLINE OF THE CALAULATION MODEL

The fundamental model of the Nays 2D Breach is iRIC Nays 2D[7] which is a two dimensional computational model for shallow water riverbed fluctuations. The model of dike break expansion progress is modified with the non-dimensional bed flow force obtained from the dike break experimental results[3] discovered using the Chiyoda experimental channel and the following relational expression of the dike collapse amount (1).

$$q_* = \frac{dV}{dt}\frac{1}{\sqrt{sgd_{50}^3}B_m}(1-\lambda) = \alpha_*(\tau_* - \tau_{*_c})^{\beta_*} \quad \textbf{(1)}$$

Where, q_*: volume of non-dimensional dike collapse, V: volume of dike collapse, t: time, s: underwater relative density of sand granules, g : gravitational acceleration, d_{50}: 50% passage grain size of sand granules, B_m: bottom width of the dike, lambda: void percentage, τ_*: non-dimensional bed flow force, τ_{*c}: non-dimensional limiting bed flow force, α_*, β_*: model constants. τ_*: is calculated from the amount of the hydraulics of the flood flow of the upstream and downstream near the dike break opening, which is used as the external force acting on the dike. From the relational expression (1) above, the dike break expansion is developed according to the calculated dV/dt of dike collapse. For details, refer to the literature of Kakinuma et. al.[9]

3. BANK BREACH OF SIBAYAMASAWA RIVER

3.1 OVERVIEW OF DISASTER AT THE SIBAYAMASAWA RIVER

Hokkaido was devastated by three typhoons in one week between August 17 and August 23 had in a week with heavy rainfall causing flood and landslide in several areas mainly in the eastern part of Hokkaido. The typhoons affected Tokoro River, causing slope failure, base water leakage from the bank embankment, and the sand blast at two of its tributaries. The bank breakage, sand blast and discharge of low water channel revetment, etc. was evident in the middle basin of Sibayamasawa River in the range of KP 12.5 ~ KP 40.0. This area is a narrow strip in mountainous terrain where water level tends to rise easily and has a river course characteristics of high water level flow continuing for an extended length. These characteristic could be the highly possible cause of the damages such as bank breach.

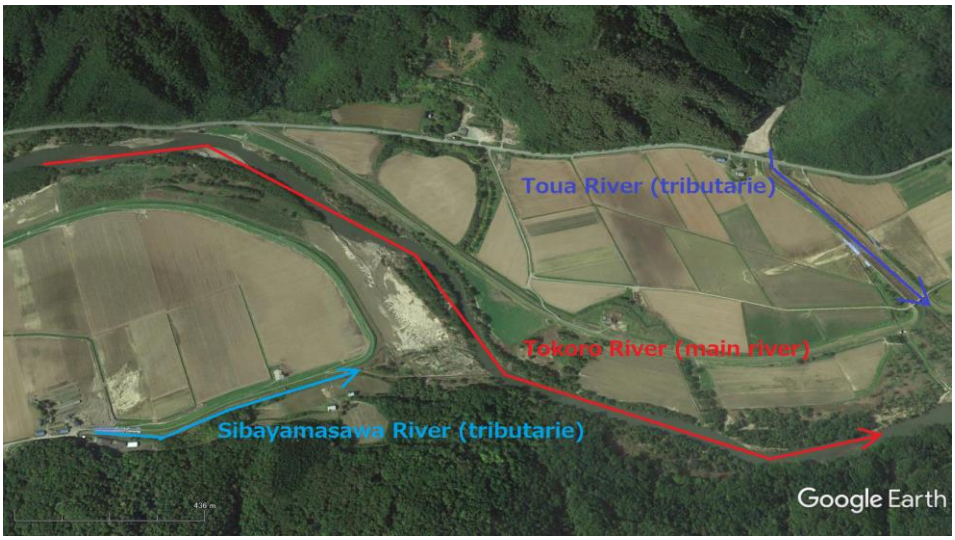

Figure 1 Location at Tokoro River and rtibutaries

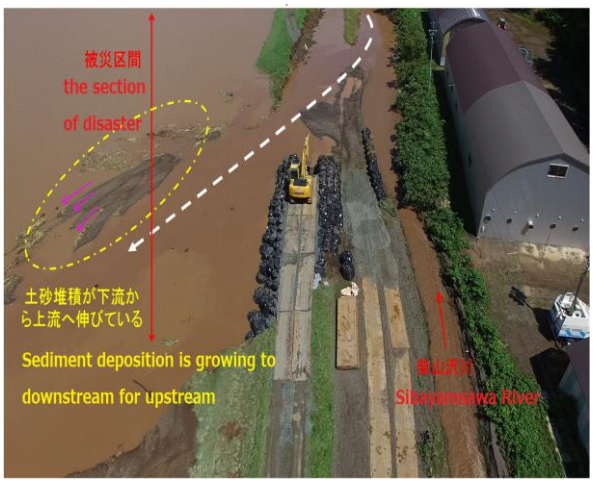

Figure2 Disaster summary at Sibayamasawa River

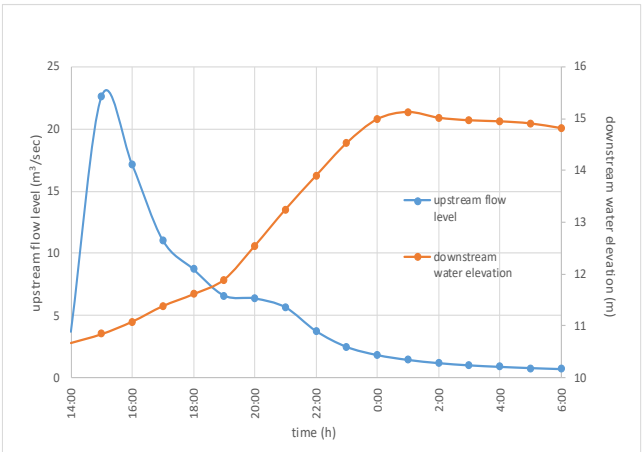

Figure 3 Sibayamasawa hydro and water elevation graph

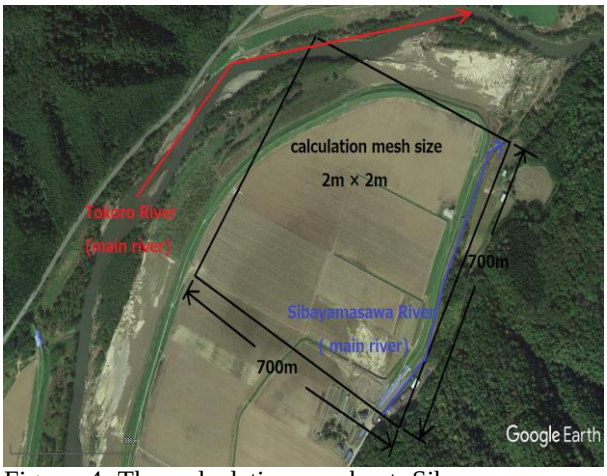

Figure 4 The calculation mesh at Sibayamasawa River

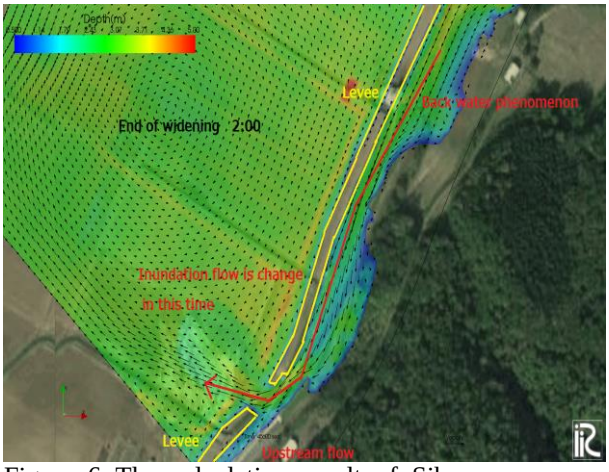

Figure 6 The calculation result of Sibayamasawa River (End of widening)

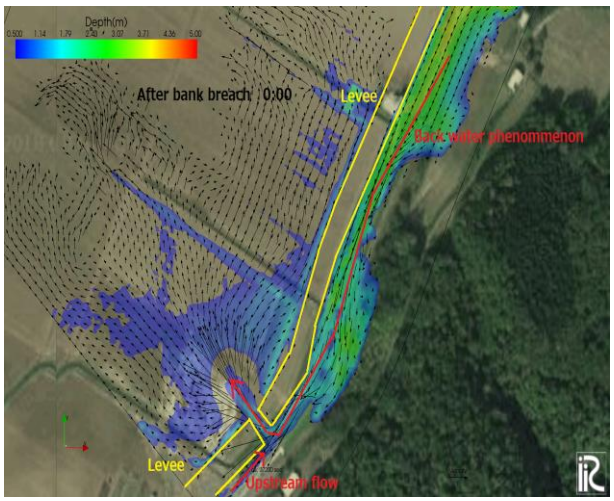

Figure 5 The calculation result of Sibayamasawa River (After bank breach)

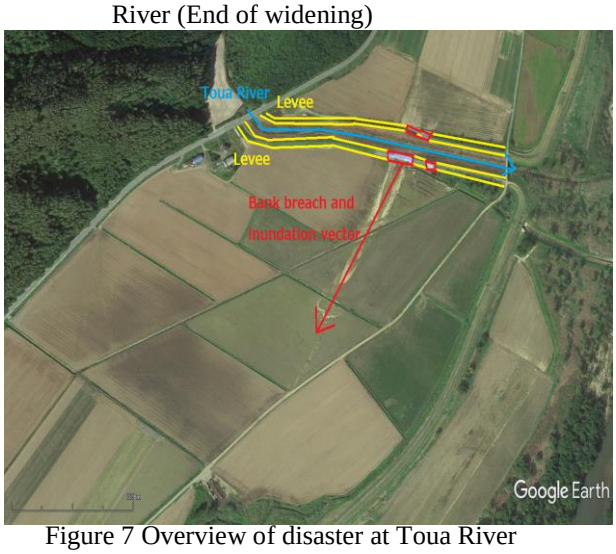

Figure 7 Overview of disaster at Toua River

The bank breach was estimated to have occurred at 0:00 on August 21[10], at which the inundation was confirmed by a manager patrolling the area and though hearing with nearby residents. Figure 2 also shows the disaster situation of Sibayamasawa River resulted in bank breach. The Figure 3 contains 2 hydro graphs of the water elevation at the junctions of Tokoro River and Sibayamasawa River and another graph to illustrate the flow of Sibayamasawa River. According to Figure 3, the estimated time of bank breach occurring at Shibusawa River isn't the time when the flow peaked in Sibayamasawa River but is much closer to the time when flow peaked in Tokoro River. It could mean that Sibayamasawa River's bank breach had a different phenomenon with which the inundation flow headed toward inland upstream. This is different from the conventional knowledge, therefore, we decided to analyse the reason behind it.

3.2 CALCULATIONAL CONDITIONS FOR SIBAYAMASAWA RIVER

The calculating area is as shown in Figure 4, set at SP400-SP1100m toward the junction of Tokoro River and Sibayamasawa River in the longitudinal direction and at 700m in transverse direction, considering the conditions about the inundation area and the stream flow at the time of the bank breach. Moreover, for Figure 4 the calculating area of Sibayamasawa River and the grid spacing is set at 2m mesh in both longitudinal and lateral directions. Here the manning roughness coefficient is set to 0.035, and the time step for calculation is set to 0.04 second. As a boundary condition, the actual results of flow at Sibayamsawa River was given for upstream and the water elevation level at the junction of Tokoro River was given for downstream. The Figure 3 illustrates the hydro of Sibayamsawa River's flow and the water elevation at the junction in the time series. The time that is the object of calculation is between 14:00 on August 20, 2016 and 6:00 on August 21, 2016, including the time of flow peak in Sibayamsawa River and the time of the highest water elevation in Tokoro River. On the calculation, conditions are set so that the bank breach occurrs when water flows over the bank levee crown at a width of 8m in the of

longitudinal distance to initiate the breaching. In addition, the material gain diameter of levee body is set to 4.8mm; and the material gain diameter of river bed is set to 1.5mm using the data obtained from the field test result of soil.

3.3 CALCULATION RESULTS OF SIBAYAMASAWA RIVER

How the behavior of inundation changed the time between the beginning of bank breach and the end of widening is compared. Firstly, the inundation situation of bank breach is shown in Figure 5. At this time, it can be confirmed that the direction of inundation flow from waterside land to inland is vertical to the levee. Once the bank breached the flow at the Sibayamasawa river is instantly almost out of flow and the bank breach occurred this time can be confirmed to have been effected by the main stream. Secondly, Figure 6 shows the behavior of inundation flow at the time of bank breach widening and here it can be seen that the inundation flow direction was changed toward the end of widening, and that the direction is changing to upstream from vertical to levee due to the effects of the Tokoro river's back water phenomenon.The inundation flow going upstream makes the upstream side of the breached section to erode and the erosion extends in the direction of the upstream side the breach point. Also, the inundation situation at the time of breaching and widening was completed is shown in Figure 6. At this stage, there's hardly any difference between the water elevation of waterside land's and inland and inundation flow decreasing with time.

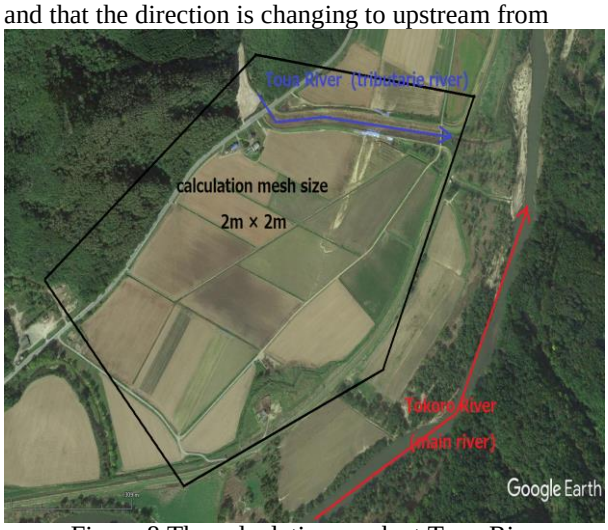

Figure 8 The calculation mesh at Toua River

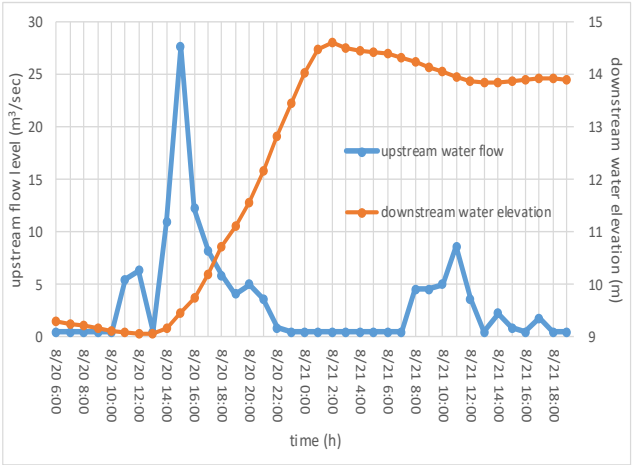

Figure 9 Toua hydro and downstream water elevation graph

4. BANK BREACHING CASE AT TOUA RIVER

4.1 OVERVIEW OF DISASTER AT THE TOUA RIVER

A total of 3 Over flow incidents occurred at Toua river. At the Toua river's right bank, the bank breached at around SP400-SP450 and the bank collapsed at the foot of slope in the region of SP350-SP365. Additionally, on the left bank, bank collapse occurred at the foot of slope between SP365 and SP374[10]. Figure 7 shows the bank conditions of the right side and the left side. Although the river characteristics are quite similar to those of Sibayamsawa, inundation flow ran in the direction vertical to the bank when the bank was breached, therefore, it can be estimated that the bank breach mechanism of Toua River is quite different to that of Sibayamsawa River. The difference is noticeable in the direction of inundation remained vertical to the bank at all times.

4.2 CALCULATION CONDITION AT TOUA RIVER

The calculation area of Toua river is, as Figure 8 indicates, includes the entire area containing the right bank and the right side of inland.

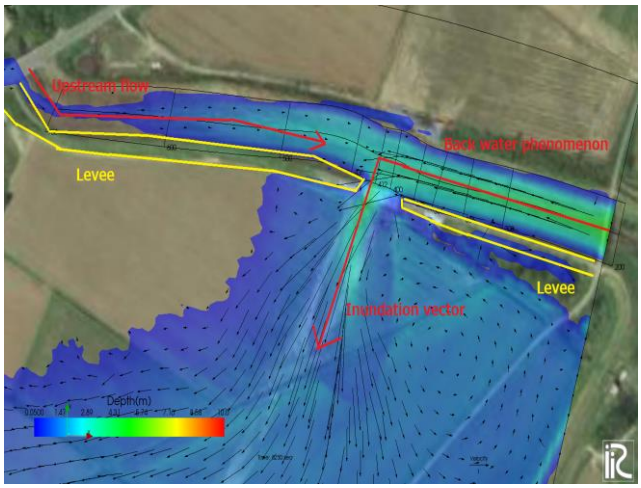

Figure 10 The calculation result at Toua River (Part of inland)

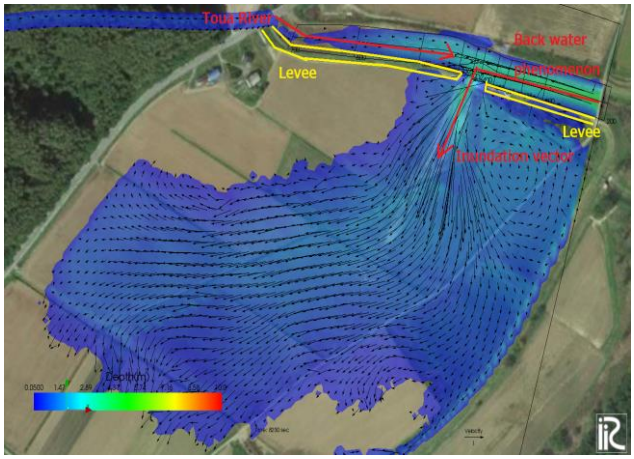

Figure 11 The calculation result at Toua River (All of the inland)

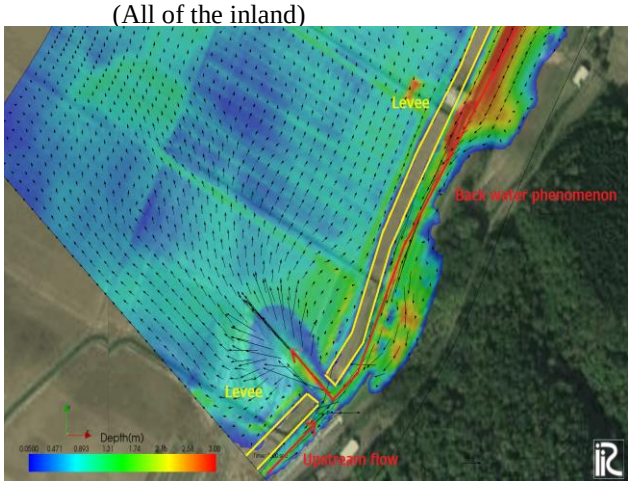

Figure 12 The calculation result of changing the upstream flow at Sibayamasawa River (After bank breach)

The calculation mesh is set at 2m grid spacing each for longitudinal and lateral directions. For this calculation the same values for manning roughness coefficient, calculation time step, riverbed material gain diameter and levee body material gain diameter was used as Sibayamasawa river. Figure 9 shows the boarding condition of the Toua river's upstream flow hydro graph and the downstream water elevation graph where the junction of Tokoro River and Toua River lies. Toua river's bank breach conditions are set similarly to those for Sibayamasawa River and the bank breach to occur at the moment of water flooding over the bank levee crown with the longitudinal distance of 8m in width to initiate the breach.

4.3 THE CALCULATION RESULT OF TOUA RIVER

For Toua River, like Sibayamasawa River, comparison of the Rivers of Toua and Sibayamsawa were made right after the bank breach and at the end of widening to see how the inundation flows. The inundation flow did not change direction and

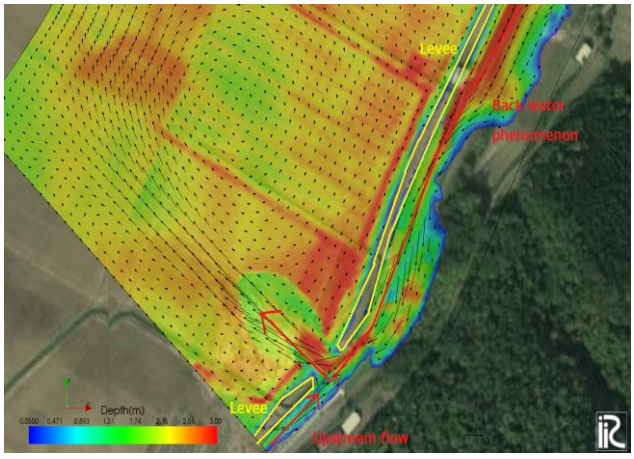

Figure 13 The calculation result of changing the upstream flow at Sibayamasawa River (End of widening)

continued to flow from waterside land to inland keeping the state of the inundation flow vertical to the bank. Figure 10 illustrates the flow state right after bank breach and Figure 11 shows the flow state of the entire inland location at that time. Studying the vector of river channel immediately after the bank breach, it can be confirmed that the water flowed in the forward direction. Moreover, it shows that the inundated flow rate is faster compared to that of Sibayamasawa river. It can be assumed that inundated water run fast in the vertical direction to bank resulted in leaving the scar far from the bank. Similar to the actual phenomena, calculation results reproduced the overflow occurring at two places on the right bank and one place on the left.

5. THE DIFFERENCE FACTOR OF BANK BREACH WITH BOTH TRIBATARIES

5.1 THE DIFFERENCE OF BANK BREACH PHENOMMENA WITH TWO TRIBUTARIES

From the result of calculation described above, with regard to inundation flow state, the flow direction in the case of Sibayamasawa River was from downstream to upstream, whereas in the case of Toua River it was at a right angle to the levee normal vector. Following the findings illustrated Figure 6 and Figure 10, it can be considered that it is the differing natural upstream flow rate that makes the difference of the mechanisms of bank breach and widening. On one side, with Sibayamsawa River's bank breach mechanism, it can be considered that the effects of back water from the main stream largely contributed to inundation flow as almost no natural flow of its own was present upstream immediately after the bank breach. On the other side, with Toua River, it is considered that the bank breach widening was affected by its own natural flow condition and back water phenomenon from the main stream as certain level of its own natural flow was present after the

bank breach. Responding to the findings stated above, the effects of the relation of upstream flow and back water phenomenon from main steam on bank breach widening mechanism were studied with the geographical features of Sibayamasawa river.

5.2 EFFECTS OF THE UPSTREAM FLOW ON THE BANK BREACH PHENOMENA

Of the reproduction calculation of Sibayamasawa river above, calculations were carried out, making changes in the condition of upstream flow level. More specifically, natural upstream flow hydro was continued to be passed with a fixed level of peak flow. The idea was to focus on the effects of the difference in the river's natural flow on the phenomena of bank breach widening, as at the natural upstream flow continued in Sibayamasawa River even after bank breach. Figure 12 shows the contour of depth and vector of velocity after bank breach. As the figure illustrates, inundation flow is running from water side land to inland at right angle against the vector of bank, this result is the same as the reproduction calculation of Sibayamasawa river. Additionally, the inundation flow velocity is faster than the reproduction calculation and this is considered that the upstream flow and the inundation flow from the main stream side to aperture is getting bigger and that makes the effects of inundation flood velocity make faster. Figure 13 shows the contour of depth and the vector of velocity when the bank breacwidening had almost ended. The time is the same as Figure 6 where reproduction calculation was carried out but the reproduction calculation of inundation flow vector travels from downstream to upstream whereas this case is different in that the inundation flow continues at right angle vector to the levee. It seems that the presence of upstream flow remains after bank breach and it collides with the back water phenomenon from main steam near the aperture of bank breach that makes it closely resembles the inundation vector to right angle from levee after the bank breach. From the above, it was clarified that difference in bank breach widening mechanism are evident even with the same point of tributaries levee that has affected section by the back water phenomenon as the tributaries own flow and flow peak appearance time differ. This indicates the need of considering multiple conditions for damage reduction measures at the time of bank breach.

6. CONCLUSION

The obtained knowledge through this research is briefly summarized below.

・The bank breach calculation model of "Nays 2D Breach

・the bank breach of Shibayamasawa River had low" enabled the reproduction of the back water phenomenon with the bank breach. level of upstream flow from tributaries and due to the effects of back water phenomenon made the inundation vector to change to right angle to bank to the upstream shown above in Sibayamasawa river reproduction calculation case.

・The condition of the upstream flow from tributaries affected the back water phenomenon making the inundation flow vector of right angle to bank immediately after bank breach widening ended.

・The fact that tributaries' own flows and back water levels affects the mechanism of inundation vector and widening vector have been confirmed from the results.

・Bank breaching and widening model of "Nays 2D Breach" enabled us to confirm the travelling direction of widening vector and inundation vector, and the details of river side flood vector after the bank breach.

REALITY IN PACKAGE ON-SITE GREASE TRAP PERFORMANCE: SUCCESS OR FAILURE IN FOG REMOVAL?

Sopa Chinwetkitvanich[1,*] and Piti Ektaku[1]
[1] Department of Sanitary Engineering, Faculty of Public Health, Mahidol University, Bangkok, Thailand

ABSTRACT

Package on-site grease traps are widely used in household and restaurant in Thailand for oil and grease removal although frequent failures in FOG removal have been reported. Theoretically, too small of operating hydraulic retention time (HRT) takes the blame, but some suppliers claim that their grease traps can be well operated even with HRT of 15 minutes. This study was to investigate the performance of grease trap with various HRTs (15 minutes to 20 hours) and FOG concentrations in the feed (50 to 600 mg/l). Results showed that the operating HRTs of 15, 30 and 60 minutes could represent a kind of shock hydraulic loading condition, which insufficient FOG removal efficiencies were observed. Also, the experiment to enhance the grease trap's performance was set up by withdrawing certain volume of grease trap waste. The operating HRT of 60 minutes with the feed contained FOG of 200 mg/l and dishwashing detergent of 0.5% (v/v) was investigated for seven-day period. The experiment without daily withdrawal was operated in parallel as a control. The results showed that the FOG removal efficiencies in the control began to fall down to 50% on the fifth day of operation. The experiment with daily withdrawal showed more stable FOG removal efficiencies, which its efficiencies was still higher than 50% after seven days of the experiment. However, this could be said that the 15-litre package on-site grease trap fed with operating HRT of 60 minutes (or lower) could not maintain sufficient removal efficiency for long period (months).

Keywords: Package on-site grease trap, Fat oil and grease (FOG), Dishwashing detergent, Oil and grease removal, Hydraulic retention time (HRT).

INTRODUCTION

Fats, oils and greases contaminated in water or wastewater are commonly referred to FOG, which can be categorized based on their origin. That is, FOG based on animal and vegetable is considered to be edible, and that based on mineral (petroleum and coal sources) is not edible. FOG in domestic wastewater is mostly generated from food processing either in household or commercial scale (e.g., restaurant, canteen, food plaza, etc.). FOG is a major problem for both onsite or public sewer systems due to it may continually accumulate and cause clogging problem within the drainage system [1]–[3]. Sometimes, clogging occurs in the crossover line between compartments of grease traps [3]. Although grease traps are supposed to remove FOG before entering a septic tank or sewer system, high FOG loads or emulsified oils as well as surge wastewater flows often cause FOG bypassing through the sewer system.

Oil contaminated in water or wastewater may exist in several forms such as free oil, physically or chemically emulsified oil, or dissolved oil. Usually, FOG in wastewater from households or restaurants is a free oil, which eventually rise to surface of the container or the receiving water. Most conventional grease traps are basically designed to allow free oil to float up to the surface. Physically emulsified oil means a free oil broken into small droplets by agitation or mixing with water. Also, high water temperatures concurred with liquid vegetable oils can promote physically emulsification. However, these physically emulsified oils will eventually separate from water again when enough hydraulic retention time is given. Chemically emulsified oil is a mixture of oil and water caused by chemical reagents, resulting in very small oil particles and not able to separate and float up to the surface of water regardless how much retention time is allowed. Kitchen wastewater may contain high chemically emulsified oil proportion due to the use of detergents and other alkalis.

The package on-site grease traps are widely used by household for oil and grease removal. Typically, a grease trap is used to intercept liquid grease waste or garbage and retain it for an adequate period of time. The configuration of the tank allows cooling down the incoming liquid, which helps solidify this grease and separation from water. However, sufficient detention time will be required to enhance an efficient floatation of this oil and grease.

In Thailand, there are several types and sizes of commercial package on-site grease traps sold in the market. However, failures of grease traps have been frequently mentioned among customers, whereas too small operating hydraulic retention time (HRT) should be the cause. Pollution Control Department

(PCD) of Thailand suggested that HRT for grease removal should not be less than 6 hours [5]. However, some suppliers declared their grease traps could be operated with design HRT of 15 minutes. Therefore, this study was to investigate a performance and optimum HRT for oil and grease removal by a package on-site grease trap. In addition, the effects of dishwashing detergent mingling in wastewater were compared.

MATERIALS AND METHOD

Synthetic oil contaminated wastewater

Cooking oil made from soybeans was used for preparation of synthetic wastewater by mixing cooking oil with tap water till the designated FOG concentrations were reached. The cooking oil was boiled for a few minutes in order to imitate used cooking oil. Then, boiled oil was diluted in tap water using mixer with speed of 110 rpm

Reactor Setup

A package on-site grease trap used in this study is a commercial type generally found in Thailand market. It was made of polypropylene (PP) with effective volume of 15 L, dimension of which was 290 mm (W) x 395 mm (L) x 330 mm (H) as shown in Fig. 1. Reactor setup consists of a 15-litre package on-site grease trap, storage influent container equipped with mixer and pump feeding, and effluent container (Fig. 2). The mixer in storage container is to prevent separation of oil from water before fed into the grease trap.

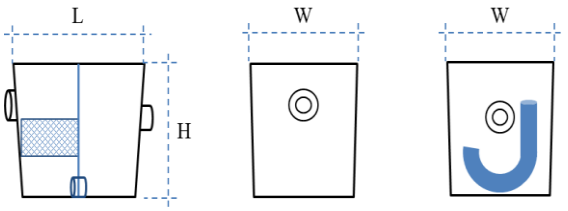

Fig. 1 A package on-site grease trap

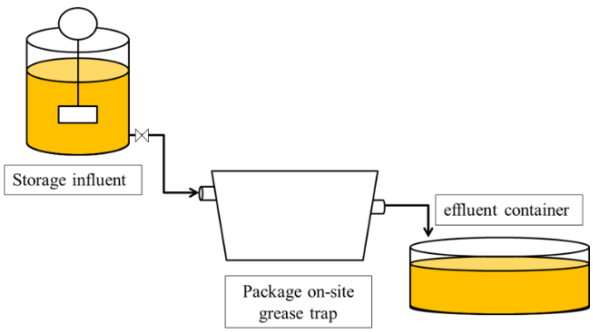

Fig. 2 A schematic diagram of reactor setup

Experimental procedures

This study was divided into two parts; the first part was to investigate effect of operating hydraulic retention time (HRT) and dishwashing detergent addition on FOG removal efficiencies. Factorial design of four FOG concentrations (50, 200, 400 and 600 mg/l) and five operating HRTs (15, 30, 60 minutes and 6 and 20 hrs.) were assigned, resulting in total of twenty experiments. Another twenty experiments were setup in parallel, with the addition of 0.5% (v/v) dishwashing detergent into the synthetic wastewater.

For experiments with HRTs of 15, 30 and 60 minutes, the synthetic wastewater was fed into the package on-site grease trap with designated HRTs for four hours continuously. Then, the feed was stopped for the rest hours of the day with the package on-site grease trap filled. Effluent samples were collected hourly and acidified for preservation till analysis. The same feeding was repeated on the next day for four days continuously. Therefore, for each operation, there were totally sixteen (4x4) samples for analysis. For experiments with HRTs of 6 and 20 hours, the synthetic wastewater was fed into the package on-site grease trap with designated HRTs. The operating hours of each day was according to HRTs, then, the feed was stopped for the rest hours of the day with the grease trap filled. The same feeding was repeated on the next day for four days continuously. Effluent samples were collected after each operating HRT was finished; therefore, there were four samples for analysis.

After four-day operation of each experiment were achieved, the reactors were cleaned to remove all residual oil attached within reactor before the operation was repeated. Each experiment was conducted in triplicates to obtained reasonably statistical results. Those samples were determined for oil and grease (as FOG) and COD according to Standard Methods for the Examination of Water and Wastewater [6].

The second part was set up to investigate the performance of the grease trap in case of daily withdrawing certain amount of floated grease trap waste was applied. The experiment was operated for seven days with selected HRT of 60 minutes for four hours each day. The synthetic wastewater composed of FOG concentration of 200 mg/l and dishwashing detergent of 0.5% by volume. Two reactors were operated in parallel, one of which was acted as a control with no daily withdrawing (named as Reactor G1), while another one was operated with daily withdrawing of certain amount of floated grease trap waste from the first compartment (Reactor G2). After seven-day operation, reactors were cleaned and the experiments were done in triplicates.

RESULTS AND DISCUSSION

Part I: Effects of operating HRT on FOG removal

Figure 3 showed the removal performance of fat, oil and grease (FOG) from the experiments with four influent FOG concentrations. The experiments with small operating HRTs, i.e., 15, 30 and 60 minutes, clearly showed less FOG removal efficiencies than the others (6 and 20 hours) either with or without addition of dishwashing detergent. That is, the daily FOG removal efficiencies with operating HRTs of 15 – 60 minutes were in the ranges of 60 – 76% and increased to the range of 88 – 94% with the operating HRTs of 6 – 20 hours in the case of without dishwashing detergent.

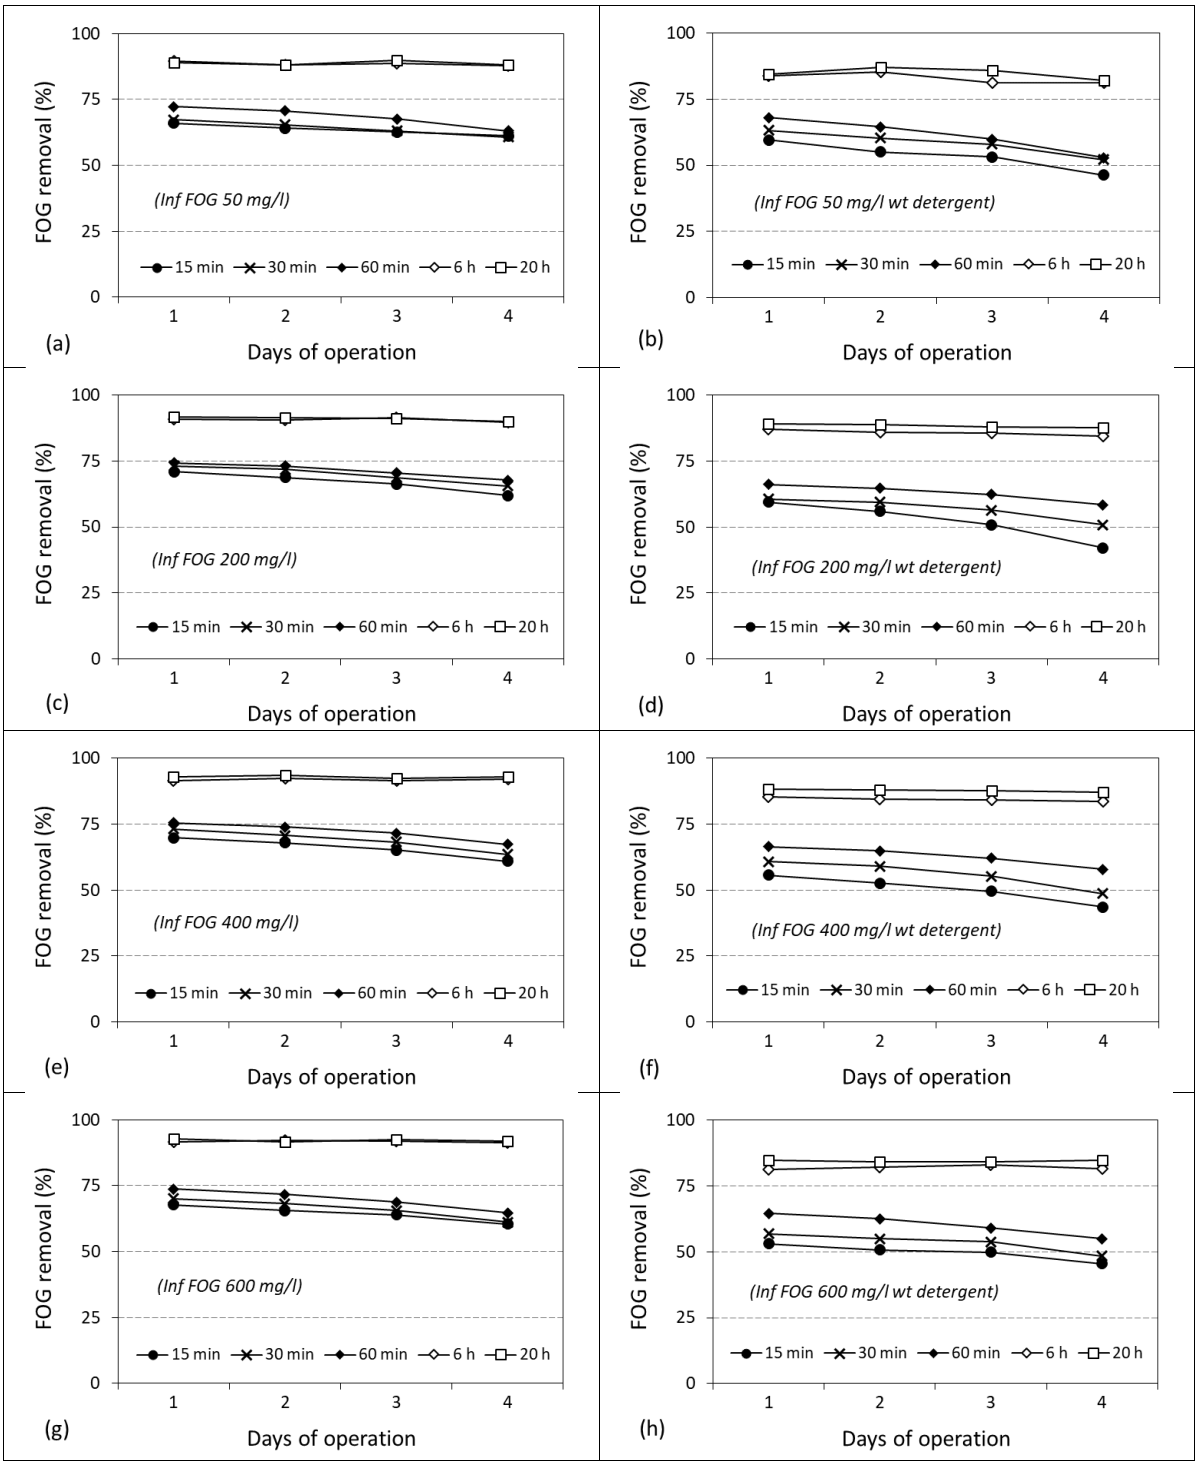

Fig. 3 Performance of FOG removals at various influent FOG concentrations and operating HRTs

Obviously, dishwashing deteriorated FOG removal performance of the trap, especially with the smaller HRTs (15 – 60 minutes). Their daily FOG removal efficiencies were in the ranges of 42 – 68% and 81 – 89%, respectively.

Table 1 concluded the averages of FOG removal efficiencies from this study. The results of both groups (without and with dishwashing detergent) illustrated that higher operating HRTs (6 and 20 hours) resulted in more FOG removal efficiencies. The variation of HRTs in the range of 15 to 60 minutes did not make substantial difference in FOG removal efficiency. The experiments with influent FOG concentration of 50 mg/l without addition of dishwashing detergent obtained a little less removal efficiencies than other concentrations. However, with addition of dishwashing detergent, their removal efficiencies of FOG 50 mg/l experiments were similar to the others.

Table 1 The average FOG removal efficiencies

Average FOG removal efficiencies (%)								
	Influent FOG concentrations (mg/l)							
	50		200		400		600	
HRTs	No D	wt D	No D	wt D	No D	wt D	No D	wt D
15 min.	63	54	67	52	66	50	64	50
30 min.	64	58	70	57	69	56	66	53
60 min.	68	61	71	63	72	63	70	63
6 h.	89	83	91	86	92	84	92	82
20 h.	89	85	91	88	93	88	92	84

Remark: D = dishwashing detergent

It could be said that the variation of influent FOG concentrations (50, 200, 400 and 600 mg/l) did not affect on the FOG removal efficiencies, especially in the same operating HRT. Consistently, Chu and Ng [7] similarly reported their COD and FOG removal efficiencies were not influenced by influent FOG concentrations ranging from 400 to 1600 mg/l. They also mentioned that a grease trap should be implemented with appropriate HRT that most of oil droplets would be separated and floated to water surface. Unfortunately, the grease trap often came across with these short HRTs in practice, especially during the peak hours of kitchen activities. Large quantities of wastewater both from meal processing or utensils washing were generated within a couple hours. This high volume of wastewater forced the grease trap to be overloaded with both high FOG concentration and hydraulic flow.

In addition, the adverse effect of dishwashing detergent was obviously found in every operating HRTs. The dishwashing detergent substantially reduced FOG removal efficiencies in comparison with the experiments without detergent, especially when the operating HRTs of 15, 30 and 60 minutes were employed. This could be explained that dishwashing detergent caused higher emulsification of oil and grease in wastewater, resulting in more difficulty to be separated from water. Thus, more retention time (or operating HRT) would be extensively required for this slower separation. Besides, hot oil and grease contaminated (from meal processing) in wastewater should be cooled within grease trap, then, they could be more solidified and easily separated from liquid bulk. Hence, short HRT in grease trap will hinder cooling step, which can double the adverse effect of short HRT on FOG removal efficiency. Therefore, the time for allowing oil and grease separated from wastewater was the key.

Part II: Effects of daily grease trap waste withdrawing

Due to oil and grease separated from the water by floating and accumulating on the surface of water, this accumulated grease trap waste required regular removal to maintain the capability of the grease trap. This experimental part was fed with the FOG of 200 mg/l and conducted with operating HRT of 60 minutes. Two reactors were set up, one of which was acted as a control with no daily grease trap waste withdrawing (Reactor G1), while another one with daily withdrawal (Reactor G2). Figure 4 illustrated profiles of the influents and effluents of FOG concentrations during seven–day operation.

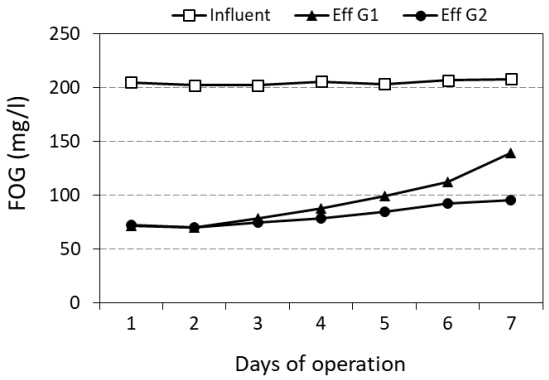

Fig. 4 Profiles of FOG concentrations

Effluent FOG concentrations of both reactors clearly increased after three days of operation. Then, effluent FOG concentrations in the control reactor (G1) gradually increased up to 139 mg/l on the last day of operation (day 7), resulting in FOG removal efficiency less than 40%. Figure 4 showed slower increase of effluent FOG in the reactor G2 (with daily withdrawing) than the reactor G1, resulting in its lower effluent FOG on the last day of 96 mg/l. It could be clearly seen that withdrawal of grease trap waste

helped reduce accumulated FOG in the trap and prolong its capability before failure. With this FOG loadings (FOG concentration of 200 mg/l, HRT of 60 minutes and 4 hours operating), the control reactor (G1) lost its 50% efficiency since the fifth day of operation while daily withdrawing could maintain FOG removal efficiency over 50% after seven days of operation.

Mass balance of FOG

Due to operating HRT of 60 minutes and four hours of operation, sixty liters of the feed were used. Therefore, total FOG mass of around 12.3 g/day were calculated and total FOG mass fed into the trap after seven days was about 86 g. For the reactor G1, which there was no daily withdrawing of grease trap waste, those retained FOG mass of 8 g on the first day was the highest, then, they declined throughout the seven days of operation (Fig 5a). Totally, accumulated FOG mass after seven-day operation was about 47 g. If density of soybean at 23.9°C was 0.9193 g/ml [8], this 47 g of retained FOG should require volume of around 51 ml (0.34% of the trap volume of 15 liter)

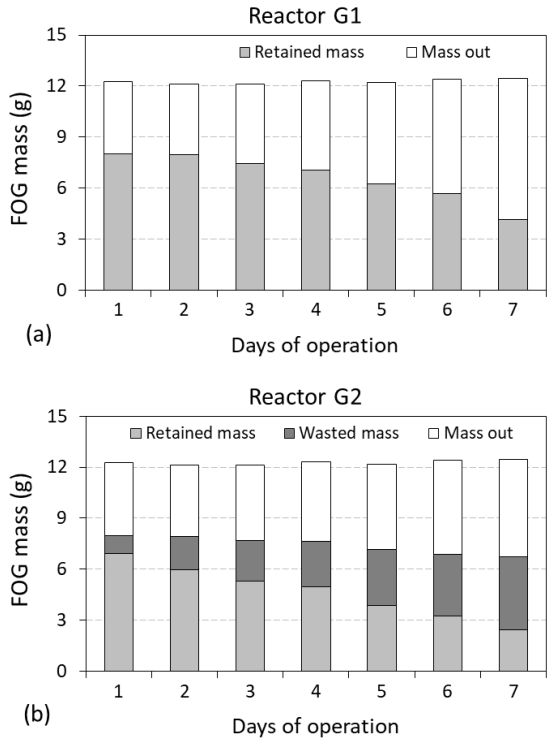

Fig. 5 Mass balance of FOG

In the reactor G2, the same seven days of operation was applied, but 0.5 liter of floated grease trap waste) was daily withdrawn. Grease trap waste mostly composed of water up to 86% [9]. The withdrawal was done in the first compartment of the grease trap (influent part). Total wasted FOG mass was about 20.3 g, considering as 23.6% of total influent FOG mass of 86 g. Apparently, daily withdrawing could help retard accumulation of retained FOG mass within the trap, resulting in less FOG mass discharged through the effluent ('mass out'). FOG removal efficiency was still higher than 50% on the last day of operation. The total accumulated FOG mass after seven-day operation was about 33 g, which was much less than those of the reactor G1 (47 g). Thus, no matter how effective grease trap was designed, lacking of proper maintenance could induce failure in FOG removal [2].

Observational opinions in configuration of commercial package on-site grease trap

From this study, there are some observational opinions about the design of the package on-site grease trap to be mentioned. That is, the difference of the traps between two sizes (15 and 30 liters) was the enlargement of the second compartment, while the first compartment of both sizes was the same dimension. Therefore, the first compartment of 15–liter grease trap acting as an inlet compartment is comparatively larger than the latter compartment (oil separation chamber). The 30–liter grease trap seems to have more suitable dimension (larger oil separation part). Unfortunately, the first compartment of 15–liter grease trap cannot be lessened because of those necessary inlet pipe and fittings. Moreover, they were also equipped with basket-shape screening for trapping food scrap or else as shown in Figure 6 [10]. Hence, the package on-site grease trap with a size as small as 15 liters would require more attention before implementation.

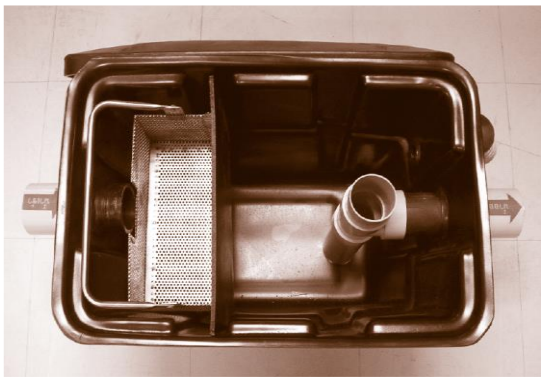

Fig. 6 Typical package on-site grease trap [10]

Besides, solid waste or food scrap contaminated in wastewater as in practice has not been included in this study. These solid wastes would be detained within the trap and deteriorate FOG removal efficiency by reducing effective volume of the trap. Also, the retained solid wastes could be further rotten and stinking within the trap faster than FOG. In practice, the small package on-site grease trap such as 15-liter type would not handle any solid wastes effectively. For this case, solid wastes or food scrap

in wastewater must be removed well enough before entering the grease trap.

In consideration of HRT equation (HRT = V/Q; where V = required tank volume and Q = hydraulic flow), hydraulic flow should be carefully selected before calculation and selection the size of grease trap. Therefore, it is important that hydraulic flow passed into the very small trap (such as 15- or 30-liter) must be carefully concerned and managed.

CONCLUSIONS

The influent FOG concentrations varied between 50 to 600 mg/l did not make substantially difference in removal efficiency of the package on-site grease trap. The operating HRTs plays an important role in FOG removal. Several operating HRTs for the grease trap were recommended and published, but some confusion occurred to users. Especially, for household level, too small operating HRT of 15 minutes used to be advertised. In practice, the package on-site grease trap commercially marketed in Thailand are mostly too small for proper FOG removal. In addition, dishwashing detergent made oil and grease more soluble, then, more difficult to separate off water. Therefore, the operating HRTs of more than 6 hours (or up to 20 hours) were recommended for reliable FOG removal. However, maintenance program for grease trap, such as regular removal of floated FOG waste, should be applied to extend their capability and prevent failure of FOG removal.

NUMERICAL SIMULATION FOR SEASONAL AND INTER-ANNUAL CHANGE OF DISSOLVED OXYGEN IN LAKE BIWA, JAPAN

Jinichi Koue[1], Hikari Shimadera[1], Tomohito Matsuo[1] and Akira Kondo[1]
[1] Graduate School of Engineering, Osaka University, Japan;

ABSTRACT

The dynamics of dissolved oxygen in lake is a fundamental issue of comprehending the water environmental habitats of aquatic organisms. In recent years, the decrease in dissolved oxygen has been observed at the bottom of the northern part of Lake Biwa, Japan. In recent years, eutrophication and global warming caused the decrease in the dissolved oxygen in the deep layer. Under these circumstances, in order to preserve the ecosystem of Lake Biwa and to provide water resources, the environmental changes in Lake Biwa should be accurately grasped. In our present study, a water quality model considering the flow field from hydrodynamic model was developed in order to grasp the concentration of phytoplankton, zooplankton, nitrogen, phosphorus, dissolved oxygen and chemical oxygen demand in Lake Biwa. Numerical simulation was carried out for 3 years from 2007 to 2009. Comparisons of the simulations with the observations showed that the seasonal and inter-annual change of dissolved oxygen was well reproduced. The dissolved oxygen decreased during decomposing the organic matter by bacteria in the bottom layer with little oxygen supply from the atmosphere and the photosynthesis from the phytoplankton under the thermocline from spring to autumn. The simulation confirmed that in each year, the dissolved oxygen was supplied in all layers by the overturning in winter.

1. INTRODUCTION

Water quality in lakes and reservoirs are of importance to daily life water but are vulnerable to external load. In various lakes, eutrophication due to increased nutrient loadings from the watershed and global warming caused deterioration of lake water quality [1] [2].

Lake Biwa which is the largest freshwater lake in Japan serves drinking water for approximately 15 million people in Shiga and other surrounding prefectures. Lake Biwa has undergone eutrophication since 1950s. After the improvement of water quality by promoting the use of non-phosphorus synthetic detergent from the late 1970s, the trends in the eutrophication in Lake Biwa had decreased. Until 1980, eutrophication was the main reason why the dissolved oxygen decreased in the deep layer. However, after the 1980s, low levels of dissolved oxygen under 2 mg/L in the bottom layer became evident. At this level, aquatic life cannot breathe naturally. The reason for the decrease in dissolved oxygen has been considered to be the strengthening of stratification due to global warming in recent years [3] [4].

The meteorological elements have direct and indirect impacts on the change of dissolved oxygen in the bottom layer. Direct impacts are due to changes in forcing factors such as air temperature, wind speed and precipitation. In particular, the rise in air temperature and the decrease in wind speed have been thought to weaken the vertical mixing of lake water, which maybe the cause of the hypoxia [5] [6].

Indirect impacts are changes in biogeochemical cycles and related biological activities. The biological metabolism to change in water temperature was observed in the deep layer after 1990, therefore the meteorological elements could cause the significant influences on the ecosystem of Lake Biwa.

In many lakes, eutrophication and climate change impacts causes the deterioration of water quality so that it is difficult to distinguish their effects [7]. It is necessary to figure out the biochemical processes together with considering the hydrological processes.

A box model was used to calculate the division of one box for the south lake and 2 boxes for the north lake in upper and lower part in Lake Biwa [8]. However, box models cannot consider spatial distribution because values in the box are uniform. The ecological simulation for the eutrophication in Lake Biwa were performed [9], [10]. It is better to use a one-dimensional model to predict long term changes in water quality ecosystem. However, three-dimensional physical processes such as the surficial flow, internal waves and turbulence caused by the wind should be included to capture the nutrient circulation.

In the present study, a water quality model considering the flow field from hydrodynamic model was developed in order to grasp the concentration of phytoplankton, zooplankton, nitrogen, phosphorus, dissolved oxygen and chemical oxygen demand in

Lake Biwa. Numerical simulation was carried out for 3 years from 2007 to 2009. The seasonal and inter-annual changes of vertical distribution of dissolved oxygen in Lake Biwa was simulated to compare with the observations from 2007 to 2009.

2. Water Quality Model in Lake Biwa

2.1 Calculation domain

This study focused on Lake Biwa in Japan. Fig. 1 shows the calculation domain and water depth in the water quality model of Lake Biwa. The horizontal domain is 36 km × 65.5 km with a horizontal resolution of 500 m. The vertical domain consists of 86 layers from the lake surface to the depth of 107.5 m. The vertical grid size is 0.5 m from the surface to the depth of 20 m and gradually increases up to 2.5 m.

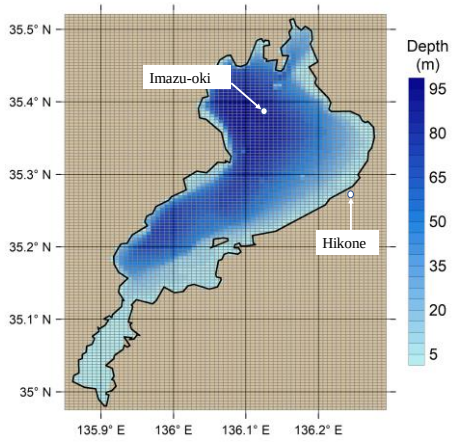

Fig. 1 Calculation domain with the topography of Lake Biwa

2.2 Each component in water quality model

Many factors are involved in water environment with large and complicated ecosystem like Lake Biwa. For simplifying this ecosystem, this model consists of nine state variables such as phytoplankton, zooplankton, particulate and dissolved organic chemical oxygen demand, inorganic and organic phosphorus and nitrogen, and dissolved oxygen. Phytoplankton have chlorophyll a, b and c. Based on the amount of each chlorophyll, the amount of phytoplankton is calculated. Phosphorus and nitrogen are two limiting nutrients that control the photosynthesis. Fig. 2 shows a conceptual diagram of a water quality model considering chemical and biological change terms.

The components are shown in Table 1. A summary of the chemical and biological processes of each component is shown in Table 2.

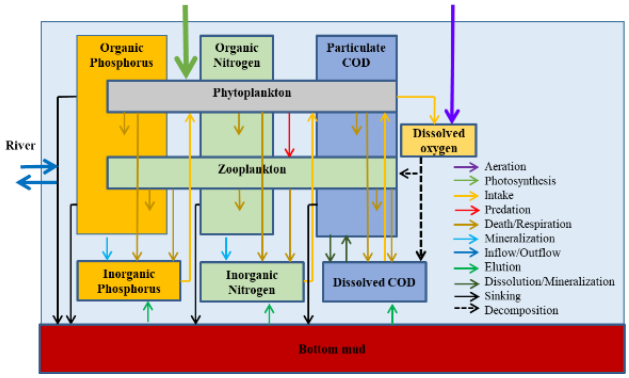

Fig.2 Conceptual diagram of water quality model

Table 1 Each component of water quality model

Component	Symbol	Unit

The advection-diffusion equation of constituent elements is shown in Equation (1). The left-hand side represents the time-varying term and the advection term, and the right-hand side represents the diffusion term and the change by the biochemical process.

$$\frac{\partial C_i}{\partial t} + u\frac{\partial C_i}{\partial x} + v\frac{\partial C_i}{\partial y} + w\frac{\partial C_i}{\partial z} = \kappa_h\frac{\partial^2 C_i}{\partial x^2} + \kappa_h\frac{\partial^2 C_i}{\partial y^2} + \kappa_z\frac{\partial^2 C_i}{\partial z^2} + Q_{C_i} \quad (1)$$

C_i : Concentration of each component
i : Component
Q_{C_i} : Amount of change per unit time due to chemical and biological processes

The formulation of material circulation for each component and the details of each term are also shown in [8].

2.3 Initial conditions

As for the initial condition, the current velocity was set to be 0 m/s. The initial concentration of each component on April 1st, 2006 was derived from linear interpolation of observed data on March 20th and April 10th, 2006. The observations were conducted by the Lake Biwa Environmental Research Institute twice a month at the monitoring point Imazu-oki (35°23'41" N., 136°07'57" E.), the depth of which was 0.5 m, 5 m, 10 m, 15 m, 20 m, 30 m, 40 m, 60 m, 80 m, approximately 90 m.

2.4 Boundary conditions

The boundary conditions for hydrodynamic model were used as the same conditions described in [11]. Air temperature, atmospheric pressure, wind direction and speed, and relative humidity over Lake Biwa were derived from the Grid Point Value produced by the Meso-Scale Model (GPV MSM) of the Japan Meteorological Agency. GPV MSM data has a spatial resolution of 0.0625° longitude by 0.05° latitude (approximately 5 km) and a temporal resolution of one hour. The data was horizontally interpolated into each surface mesh of the hydrodynamic model. Solar radiation was derived from hourly observation data at the Hikone Local Meteorological Observatory (35°16'30" N, 136°14'36" E), (Fig. 1). Solar radiation was assumed to be horizontally uniform over the lake. The water temperature and flow rate simulated by the Yodo river basin model [12] were used as the boundary conditions for 56 rivers flowing into Lake Biwa.

2.5 Simulation conditions

The data of water temperature, flow direction, and flow velocity used in water quality model are input using the calculation results of the flow field model every three hours, and the calculation results of each component from the Yodo river basin model are used for the inflow from the river. The simulation was conducted for a period from 1st April 2007 to 31st March 2010 (Japanese fiscal year (JFY) 2007 to 2009) with a spin-up period from 1st April 2006 to 31st March 2007 using meteorological data derived from GPV MSM. Table 3 shows the simulation conditions for water quality model. The parameters of chemical and biological processes are based on [8].

Table 3 Simulation conditions for biological model

Parameter		Condition
Time step		45 s
Output interval		Every 3 hour
Horizontal grid size		500 m
Vertical grid size		0.5-2 m
Meteorological Data		GPV MSM data
Flow field data		Hydrodynamic Model
Inflow from river	Dissolved oxygen	Observed data from Ado river

3. RESULTS AND DISCUSSIONS

3.1. Seasonal change of nutrients and dissolved oxygen at Imazu-oki

Fig. 3, 4 and 5 show the seasonal changes in vertical distribution of observed and simulated total nitrogen (TN), phosphorous (TP), and dissolved oxygen (DO) at the monitoring point in Imazu-oki in 2007. The vertical distributions of TN, TP, and DO each year are not very different from each other, therefore we picked the values in 2007 as a representative year. The concentration of TN in the simulation didn't change seasonally above the thermocline. This may be because the amount of intake of inorganic nitrogen by phytoplankton was not enough in summer and autumn in this model. The concentration of TP in the simulation at the bottom layer was underestimated. The possible reason for it is that the amount of elusion in the bottom layer was not sufficient in this model. On the other hand, the trend of vertical distribution of DO in the simulation was well reproduced. In a stratified season, DO decreased under the thermocline while the organic matter was decomposed. In winter, DO increased because of the supply of the oxygen from the upper layer during overturning.

3.2. West-east vertical cross sections through Imazu-oki for DO in the simulation

The distributions of simulated DO along the line passing from west to east through the monitoring point in Imazu-oki are shown in Fig. 6. The snapshots were taken at 12:00 p.m. from April 2007 to February 2008 every two months. DO in the eastern coast tended to decrease from spring to autumn compared with the one in western side. One reason for it was the water temperature increased more in the eastern coast and less oxygen could be dissolved in water. The other reason for it was that since the slope in the eastern coast was more moderate than that in the western side, the organic carbon in the bottom layer was accumulated more in the eastern coast than in the western coast.

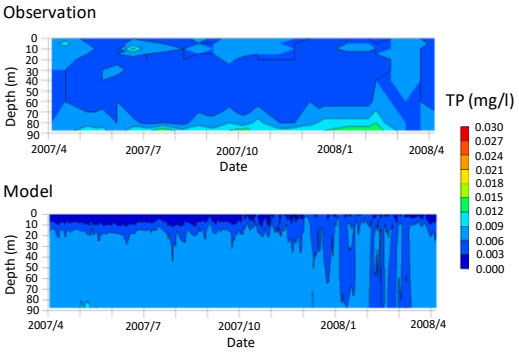

Fig. 4 Seasonal change of vertical distribution of observed and simulated total phosphorous at Imazu-oki in 2007.

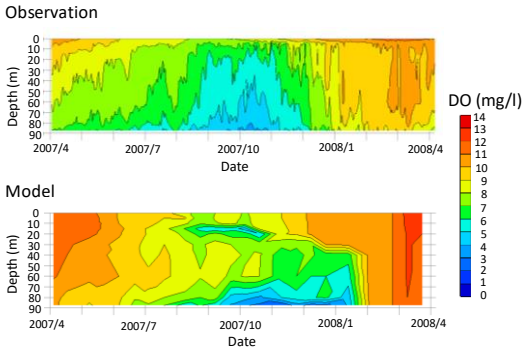

Fig. 5 Seasonal change of vertical distribution of observed and simulated dissolved oxygen at Imazu-oki in 2007.

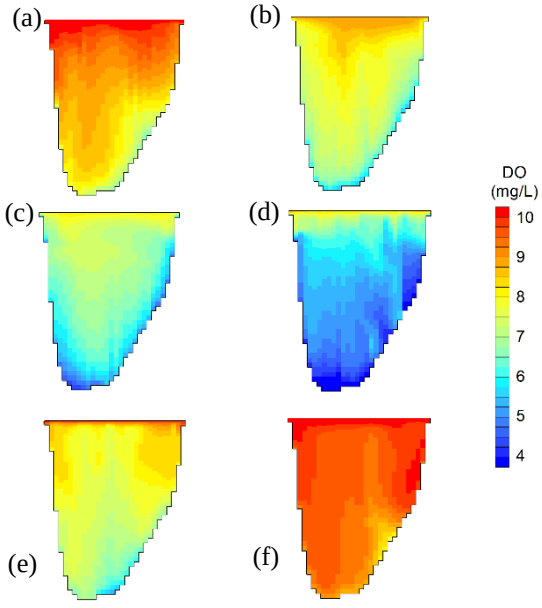

Fig. 6 Seasonal change in vertical distribution of simulated dissolved oxygen (Color contour: dissolved oxygen (mg/l)) (a) 3rd April; (b) 4th June; (c) 6th August; (d) 1st October; (e) 3rd December; and (f) 4th February.

3.3. Inter-annual change of DO at Imazu-oki

Fig. 7, 8 and 9 show the inter-annual changes in vertical distribution of observed and simulated TN, TP, and DO at depths of 0.5 m, 20 m, and 90 m at the monitoring point in Imazu-oki. The inter-annual change of TN was not well reproduced because the parameter of intake of inorganic nitrogen could be a small value during photosynthesis every year. The inter-annual change of TP in the simulation didn't agree well with the one in the observation in the bottom layer, because the amount of elution from the bottom of the lake could be insufficient. The inter-annual change of DO in the simulation approximately agreed with the one in the observation above the thermocline. In the surface layer, the seasonal change of DO was influenced by the dissolution rate.

The saturated concentration of DO is 11.8 mg/l in 8°C water in winter and 7.8 mg/l in 28°C water in summer every year. DO in the bottom layer decreased during decomposing the organic matter by bacteria with little oxygen supply from the atmosphere and the photosynthesis from the phytoplankton from spring to autumn every year. DO was supplied in all layers by the overturning in winter and the timing of recovery of DO depended on the start of overturning. The difference of DO between simulation and observation in the bottom layer possibly derived from not giving enough parameter values of consumption of DO during decomposing organic matters.

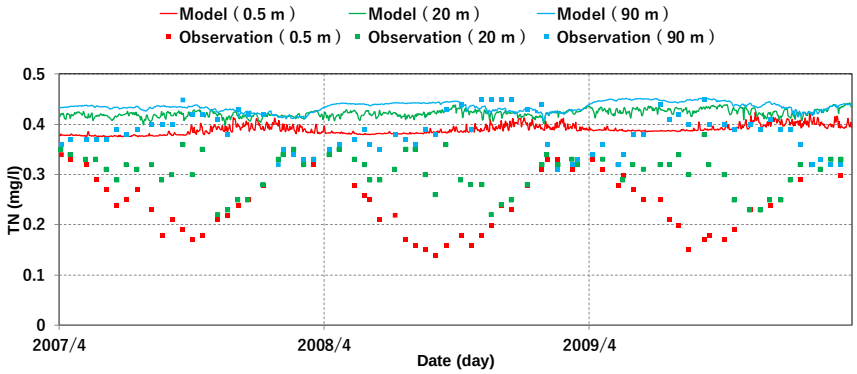

Fig. 7 Inter-annual change of vertical distribution of observed and simulated total nitrogen at Imazu-oki.

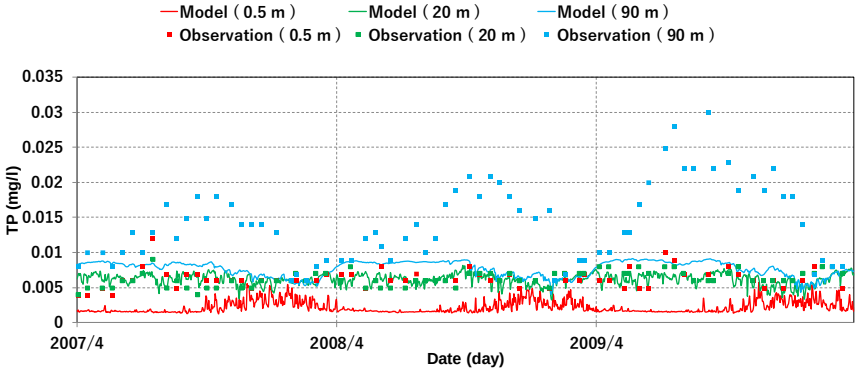

Fig. 8 Inter-annual change of vertical distribution of observed and simulated total phosphorous at Imazu-oki

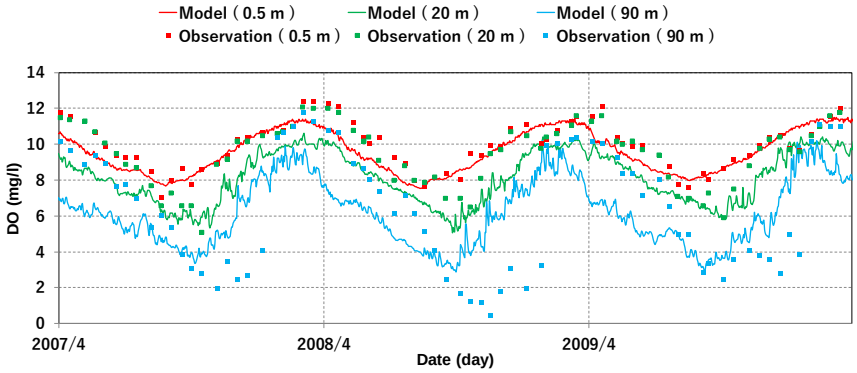

Fig. 9 Inter-annual change of vertical distribution of observed and simulated dissolved oxygen at Imazu-oki.

4. CONCLUSION

A three-dimensional water quality model considering the hydrodynamic processes is necessary for understanding the dynamic analysis of DO in Lake Biwa. Numerical simulations were carried out for 3 years from 2007 to 2009. This model was based on a low trophic level ecosystem. It consisted of phytoplankton, zooplankton, nitrogen, phosphorus, dissolved oxygen and chemical oxygen demand as state variables. In this model, the inflow load from the river was considered and the vertical mesh was in detail for reproducing the thermocline which suppressed the transportation of the substances.

The trend of the seasonal changes in the vertical distributions of DO were approximately reproduced by the water quality model considering the flow field. The simulated DO concentration above the thermocline approximately agreed with the observed one. DO solubility in water is influenced by the water temperature. In the surface water, DO was always saturated. As water depth increased, DO decreased due to the thermocline suppressing the transport from DO in the upper layer. The dynamics of DO above the bottom of the lake was controlled by consumption by bacteria and the supply from DO in the upper layer during overturning.

In order to better reproduce observed DO, minimal and maximal growth temperatures of phytoplankton and bacteria should be considered more in detail. Water temperature affects the biological processes such as algal growth, photosynthesis and decomposition of organic matters which cause the change in oxygen at the bottom of the lake.

As for TN and TP, there was a difference between simulation and observation, because the amount of intake by phytoplankton and mineralization of organic matter could be different from the observed ones. In order to reproduce the change in nutrients concentrations more precisely, the water quality model should consider the biochemical processes in detail to give the exact parameter and include the model of transportations of nutrients at the boundary conditions between bottom water and sediments. The decrease in DO at the bottom of the lake triggers the elution of nitrogen and phosphorus from the bottom sediment.

The model which can reproduce the seasonal and inter-annual change in concentrations of nutrients accurately leads to clarifying the reason why DO in the bottom of the lake decreased in a certain year. It is important to elucidate the effects of global warming and eutrophication. That leads to preserving the water quality and ecosystems of Lake Biwa.

ABSTRACT

The Energy Policy and Planning Office, Ministry of Energy, Royal Thai Government reported that from 2007 to 2015, the using of fuel increase in every year. In addition, the price of fuel increases continuously. The way of most efficiently of energy using is important. This paper aimed to study about the thermal efficiency of infrared gas stove by varies with the parameters which were diameters of pot (220, 240 and 260 mm), distances between burner (20, 25 and 30 mm) and pot and diameter of burner head (135, 145 and 155 mm) in 9 cases by simulation method. The numerical model was validated with the results from the experiment in 220, 240 and 260 mm of diameter of pot, average error are 10.85011, 6.754703 and 2.13054 percentages, respectively. The results of this study showed that with three sizes of pot, huger distances between burner and pot decrease thermal efficiency. The highest thermal efficiency was in 260 mm of diameter of pot. Within 9 cases by vary the parameters, the highest thermal efficiency was 260 mm of diameter of pot, 20 mm of distance between burner and pot and 145 mm of diameter of burner head condition and the less thermal efficiency was 220 mm of diameter of pot, 20 mm of distance between burner and pot and 145 mm of diameter of burner head condition. The obtained results provide useful for the development of heating process by infrared burner technologies and to guide the development of effective infrared burner too lead the way in energy-saving way and reduce environmental impacts.

Keywords: Infrared Gas Stove ; Temperature Distribution ; Thermal Efficiency ; Finite Element

INTRODUCTION

Data from the Energy Policy and Planning Office, Ministry of Energy, Royal Thai Government found that the usage of fuel gas in the year 2007 to 2015 is likely to increase every year [1]. In addition, the price of fuel gas in Thailand was found to have a tendency to rise every year as well [2]. However, because energy is limited, in order to reduce the energy consumption of the country should be find ways to use energy most efficiently as possible.

Infrared burner is a type of low gas pressure. The working principle of infrared burner is relying on heat transmission by radiation. Infrared (IR) is a part of the electromagnetic spectrum. IR is invisible radiant energy, electromagnetic radiation with longer wavelengths than those of visible light, extending from the nominal red edge of the visible spectrum at 700 nanometers (frequency 430 THz) to 1 mm (300 GHz). From survey the market, it is found that the infrared burner that supplied in Thailand all have the same type of radiation is the release of gas using ceramic plate [3]. The other characteristics are not as popular or widespread in the country because the producers lack knowledge and technology in production. Current infrared burner is gaining more popularity in households due to the infrared burner is a low gas pressure of no flames. The advantages of infrared burner are reducing the consumption of cooking gas stove over conventional, characterized by burning smokeless, clean applications and can be easily controlled as desired. Results in the annual sales volume of all operators in Thailand of infrared burners is 430,000 stoves per year.

Many previous researches studied on drying products using infrared radiation. The study found that drying using infrared reduces drying time less than the traditional drying (using hot air). There are some researches described the basic principles of infrared radiation and applications in the food industry such as baking, roasting and drying, the study found that the infrared can transfer heat to the food more efficiently and it can be reducing the time and cost of process [4-6]. It was also found that the products from infrared heating have better quality than conventional heating [7]. The rate of gas consumption was compared during the cooking of meat products using a gas stove with a traditional model and an infrared gas burner of ceramic plates [8]. It is observed that the infrared gas burner can help reducing gas consumption by about 55%. However, a few studies considered model of heat transport during heating by infrared burner,

especially a detailed study of the effect of heating time, temperature of the burners, the distance between the burners and the boiling pot of water and the size of the burners on temperature distribution and thermal efficiency of the infrared burner. This is because complexity of the mathematical model of pot and infrared burner

In this study, the influences of diameters of pot, the distances between the burner and the boiling pot of water and the size of the burners on temperature distribution and thermal efficiency during heating using infrared burner are investigated. In order to verify the accuracy of the present model, the computer simulation study is validated with an experimental study. The test method is reference from the low-pressure gas burner in households with LPG test (TIS No. 2312-2549) and the Development of energy efficiency standards infrared burner project. An axially symmetric model of pot and infrared burner are considered in this study, which minimized the computation time while maintaining good resolution and represents the full 2-D result. The governing equations as well as initial and boundary conditions are solved using the axisymmetric finite element method (FEM). The results of the study will be the basis for the study and analysis the effects of various parameters on temperature distribution and thermal efficiency during heating using infrared burner.

EXPERIMENT SETUP

For experiment, the test method is referenced from the low-pressure gas stove in households with LPG test (TIS No. 2312-2549) and the Development of energy efficiency standards infrared burner project [3].

The experimental testing apparatus

Infrared gas stove is used in the experiment. The infrared gas stove is composed of ceramic plate that it emits heat to the pot. The infrared gas stove that was used in the experiment was shown in Fig. 1. In this experiment, the three sizes of aluminum pots (220, 240 and 260 mm) as shown in Fig. 2 are used to compare the temperature and thermal efficiency.

Fig. 1 Infrared gas stove which is used in the experiment.

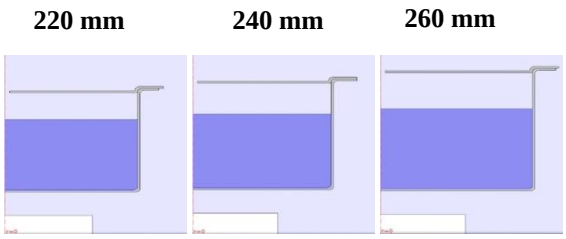

Fig. 2 Aluminum pots for experimental study.

Experimental methods to determine the thermal efficiency of the infrared gas stove in this study are in the Fig. 3 and follow by the steps. Starting with check and prepare experimental equipment, set up stove and connect the stove with gas gauge, pressure equipment, gas temperature gauge and valve gas as shown in Fig. 4. Then adjust the gas valve to the maximum gas inject position at gas pressure of 280 millimeters water (mm H_2O). Warm the burner for 5 minutes to remove stains dirt and oil. Turn off the stove and place the pot on the center of stove then put the thermometer to measure temperature. The initial water temperature should be set up at 25 ± 2 °C. In addition, the testing room is controlled room temperature at 25 ± 2 °C. Before the test, the temperature of gas and water temperature are recorded. The position for measuring the temperature of the center of the water at the height of 5 mm from the bottom of the pot is considered. Follow this procedure until the temperature of water increase from initial for 50 °C. Finally, turn off the stove; record the last temperature of water and quantity of gas. An experiment is repeated 5 times. The data of the test will be used to calculate the thermal efficiency of infrared gas stoves. Before do the test again, pot cleaner clearly to minimize heat loss. The temperature measured in experimental is recorded by using digital thermometer during heating. The dimension of pot and infrared gas stove and conditions in this experiment setup is used for the simulation.

Fig. 3 The water in the container is boiled in the experiment.

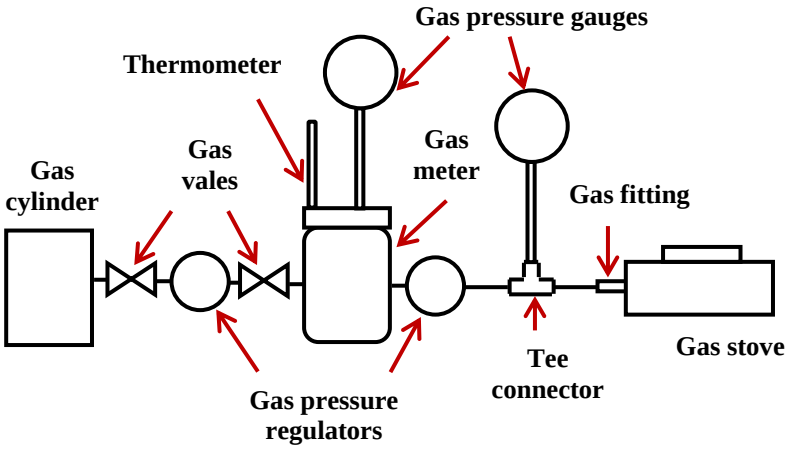

Fig. 4 Experimental apparatus.

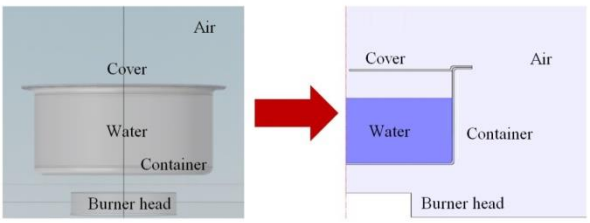
Physical model

Analysis of heat transfer in water during heating by using infrared gas stove is presented. The system of governing equations as well as initial and boundary conditions are solved numerically using the FEM via COMSOL™ Multiphysics. In order to verify the accuracy of the present model, the simulation results are validated against the experimental results with the same conditions. The mathematic model used in computer simulation is divided into two parts, namely a container (pot) and infrared gas stove as sown in Fig. 5. The pot made of aluminum material. Because of the pot and burner are cylinder shape and the pot are located on the center of burner, an axially symmetric model is considered in this study for save the computation time. The axially symmetric model of pot and infrared gas stove for heat transfer analysis of water heating by using infrared gas stove is proposed. Heat absorbed by the water and converted into internal heat generation, which causes its temperature of water to rise. The convergence test is carried out to identify the suitable numbers of element required. The properties of materials are based on properties of equipment that use in experiment. There are properties of air, water and aluminum as shown in Table 1.



(a) (b)

Fig. 5 The numerical model that used in the simulation (a) 3D model and (b) 2D axial symmetry model.

Table 1 The properties of materials [9-11].

Properties	Air	Water	Aluminum
Density (kg/m^3)	1.186	1000	2700
Heat capacity (J/kg·K)	1005	4186	897
Thermal conductivity (W/m·K)	0.0259	0.6065	204

Equations for heat transfer analysis

The heat transfer model is developed to predict the temperature distribution in the water. The assumptions have been offered for computer analysis is as follows: lack of the combustion of gas fuel, unconsidered a container base and no phase change and no chemical reaction in the water. Also, thermal properties of water, aluminum pot and air are constant. Fig. 6 shows the internal and external boundary condition of pot. Temperature boundary condition is to specify the temperature from the burner head. The boundary condition of heat continuity is to temperature continuity in the different domain. The specification of the insulate boundary is in thermal insulation boundary condition. The inlet condition is to add the velocity to the model. The condition outflow is used in the flow problem with the unknowns of flow velocity and pressure. The boundary condition of wall is specific $\vec{u} = 0$. The open boundary is used to specify at the outlet. The initial condition of water is defined as $T_0 = 25$ °C at $t = 0$ s in order to comply with the experiment. The simulation measured point of water temperature to find thermal efficiency and water velocity measured point at 5 mm above inside bottom of pot.

The governing equation describing the heat transfer phenomenon is given in Eq. (1):

$$\rho c \frac{\partial T}{\partial t} + \rho c \vec{u} \cdot \nabla T = \nabla \cdot (k \nabla T) = 0 \qquad (1)$$

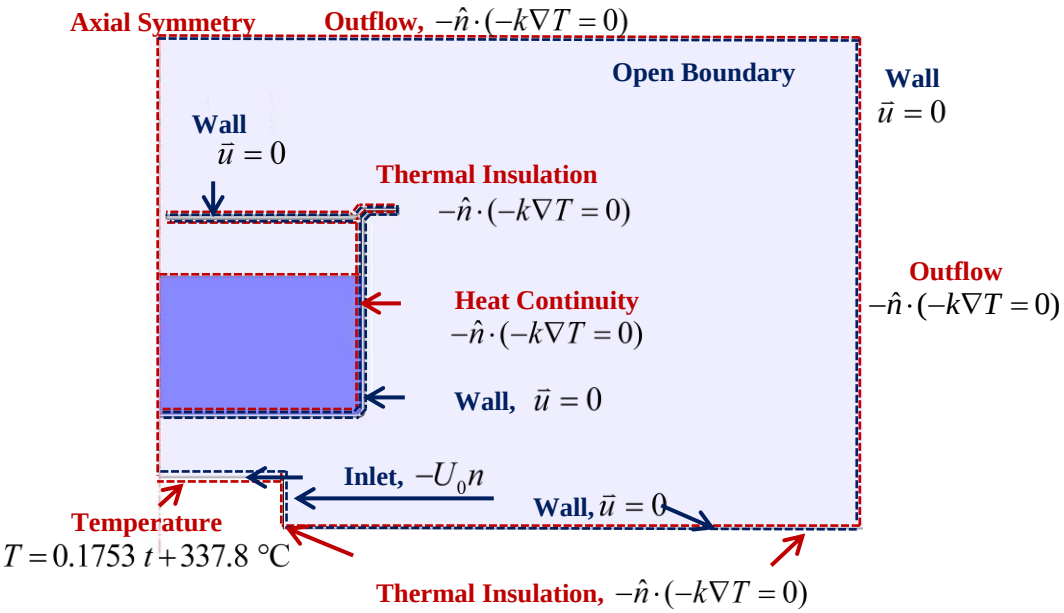


Fig. 7 Boundary condition for numerical analysis

Where ρ = 1000 kg/m^3 is the density, c = 0.004186 MJ/kg.K is the specific heat capacity, T is the temperature (°C), t is the time (s), $\vec{u}$ is the velocity (m/s) and k = 0.6065 W/m·K is the thermal conductivity.

Corresponding to heat transfer analysis, fluid flow analysis inside the water and air is assumed in axially symmetric model. Fluid flow analysis is formulated to describe the water and air velocity distributions. Using standard symbols, the governing equations describing the fluid flow are given as follows:

Continuity equation:

$$\frac{\partial \rho}{\partial t}+\nabla\cdot\left(\rho\vec{u}\right)=0 \tag{2}$$

Navier-Stokes equation:

$$\rho\frac{\partial u}{\partial t}+\rho(\vec{u}\cdot\nabla)\vec{u}= \nabla\cdot\left[-pl+\mu\left(\vec{u}+\nabla\vec{u}\right)^T-\frac{2}{3}\mu\left(\nabla\cdot\vec{u}\right)l\right] \tag{3}$$

Where ρ is the density (kg/m^3), t is the time (s), $\vec{u}$ is the velocity (m/s), p is the pressure (Pa), μ is the viscosity (Ns/m^2) and l is the identity matrix tensor.

The equation for calculate the thermal efficiency is given in Eq. (4) [1]:

$$\eta=\frac{m\times c\times(T_2-T_1)}{V\times Q}\times\frac{273+T_g}{298}\times\frac{101.3}{P_s+P_m-P_{sat}}\times 100\,\% \tag{4}$$

When η is the thermal efficiency (-), m is the mass (kg), c = 0.004186 MJ/kg.K is the specific heat capacity, T_1 = 25 ± 2 °C is the initial temperature of water, T_2 = 75 ± 2 °C is the final temperature of water, V is the amount of gas used test (m^3), Q = 107.86 MJ/m^3 is the lower heating value, T_g is the temperature of the gas during the test (°C), P_s is the atmospheric pressure during test (kPa), P_m is the pressure of the gas during the test (kPa), P_{sat} is the pressure of saturated stream at a temperature of gas during test (kPa).

RESULTS AND DISCUSSION

Verification of the Model

The number of elements where solution is independent of mesh density is found to be 26,754 elements. It is reasonable to confirm that, at this number of elements, the accuracy of the simulation results is independent from the number of elements through the calculation process. The water temperature during boiling the water with the infrared gas stove of the experimental study and

numerical study in condition pot size 220, 240 and 260 mm, distance between burner and pot 25 mm and diameter of burner head 145 mm are shown in Table 2, Table 3 and Table 4, respectively. The water temperature of the experiment and simulation (experiment:simulation) at 720 s of 220, 240 and 260 mm of pot size are 70.1:61.095, 65.2:60.55 and 57.7:61.19, respectively. The average error between the experimental results and simulation results of water temperature with the different 220, 240 and 260 mm of diameters of pot are 10.85011, 6.754703 and 2.13054 percentages, respectively. The average error of the experimental result and simulation results is part of the initial water temperature. The initial temperature of the simulation is specified at 25 °C but the experimental initial temperature is 25 ± 2 °C. It is found that the results of experiment and simulation are consistent. The results also indicate that an increase in the heating times results in an increase temperature. Even though there have a little different, the both of trends is similar. Therefore, this model can use to analyse and study thermal efficiency of infrared gas stove.

Effect of parameters varying

The different parameters are studied with the numerical method to compare the water temperature and thermal efficiency. The different pot sizes (220, 240 and 260 mm), distances of the burner and pot (20, 25 and 30 mm) and the diameters of burner head (135, 145 and 155 mm) are studied in 9 cases which are shown in Table 5. When the parameter changes, the other parameters are constant. For example, in the first three cases, the diameters of pot are 220, 240 and 260 mm with the constant parameters of 25 mm of distance between burner and pot and 145 mm of diameter of burner head. The cases number 2, 4 and 8 are in the same conditions because there is one vary parameter with two constant parameters.

The effect of parameters of diameters of pot (220, 240 and 260 mm), distance between burner and pot (20, 25 and 30 mm) and diameters of burner (135, 145 and 155 mm) to thermal efficiency of an infrared burner were studied in this research in 9 cases as shown in Table 5. In various parameters, the other parameters are fixed. The bigger pot size has thermal efficiency more than the small pot size. The thermal efficiency in the small gap between burner

and pot is higher than the widely size. In various diameters of burner head, the middle size which is 145 mm has the thermal efficiency more than the other sizes. Figure 8 shows the comparison of thermal efficiency by parameters varying.

Table 5 The thermal efficiency of infrared burner with varying parameters which are diameters of pot (220, 240 and 260 mm), distances between burner (20, 25 and 30) and pot and diameter of burner head (135, 145 and 155 mm).

Case	Diameters of pot size (mm)	Distances between burner and pot (mm)	Diameters of burner head (mm)	Thermal efficiency (%)
1	220	20	145	46.452
2	240	20	145	56.863
3	260	20	145	56.891
4	240	20	145	56.863
5	240	25	145	54.680
6	240	30	145	53.531
7	240	20	135	50.684
8	240	20	145	56.863
9	240	20	155	54.671

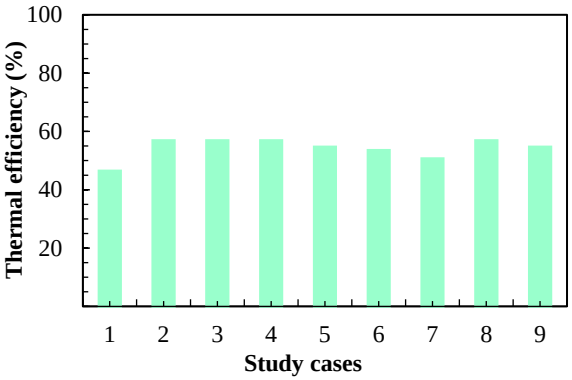

Fig. 8 Comparison of thermal efficiency by parameters varying.

The graph of thermal efficiency of parameters which are diameters of pot, distances between burner and pot and diameters of burner head is shown in Fig 8. When compared the thermal efficiency in various diameter of pot and distance between burner and pot conditions, the results of various size of pot have the difference more than the other parameters. The highest thermal efficiency of 9 cases is 260 mm of diameter of pot, 20 mm of distance between burner and pot and 145 mm of diameter of burner head at 56.891 percentages and the minimum thermal efficiency is 220 mm of diameter of pot, 20 mm of distance between burner and pot and 145 mm of diameter of burner head condition at 46.452 percentages.

Figure 9 shows the temperature distribution of 9 cases studied. The temperature distributions above the burner head of 155 mm of diameter of burner head are higher than the temperature distributions of 145 and 135 mm. The small head of burner and less area for heat transfer than the huge diameters of burner head and final temperature of water agree with the heat transfer. However, temperature distribution of 135 mm of diameter of burner head is different from the other burner head sizes. The area of head of burner and bottom of pot make the shape of temperature distribution different from the 145 and 155 mm of diameters of burner head. Water temperature of 135 mm of diameter of burner head is less than water temperature of 145 mm and 155 mm, respectively. In addition, the water temperature of small gap between burner and pot is more than water temperature of the huge distances between burner and pot. The huge distances between burner and pot have longer distance to transfer the heat than the small distance and have an opportunity for heat loss to surrounding more than little distance.

CONCLUSIONS

Thermal efficiency of infrared burner in varying of parameters which are diameters of pot (220, 240 and 260 mm), distances between burner (20, 25 and 30 mm) and pot and diameter of burner head (135, 145 and 155 mm) are studied in this research. The 26,754 elements are used in this simulation and are compared with the experimental results.

(1) This numerical model can solve the results of the heating of water by infrared gas stove. The average error of water temperature between simulation results and experimental results in 220, 240 and 260 mm of diameter of pot are 10.85011, 6.754703 and 2.13054 percentages, respectively.

(2) The parameters are effect to the water temperature and thermal efficiency. In 9 cases by varying of the parameters, the simulation results show that the less distances between burner and pot increase thermal efficiency of infrared burner and the highest thermal efficiency was in 260 mm of diameter of pot condition.

(3) The 260 mm of diameter of pot, 20 mm of distance between burner and pot and 145 mm of diameter of burner head has the maximum thermal efficiency and the 220 mm of diameter of pot, 20 mm of distance between burner and pot and 145 mm of diameter of burner head condition has the minimum thermal efficiency.

The complete mathematical model is useful for the development of heating process by infrared burner technologies and is a way to increase the thermal efficiency of various devices

EVALUATION OF BUS RAPID TRANSIT (BRT) TRANS KOTA TANGERANG SERVICE PERFORMANCE

Bella Fauziah[1], Lita Sari Barus[2] Jachrizal Sumabrata[3]
[1]Urban Studies, University of Indonesia, Jakarta.

ABSTRACT

The Tangerang City Government is one of the cities that has implemented BRT policy as public transportation since December 2016. However, its operation is considered to be lonely. This study aims to assess and analyze of BRT Trans Kota Tangerang Service Performance. The study used a quantitative method with servqual analysis to find out the comparison between expectations and reality from the service side with data analysis techniques using SEM analysis. From the results of the analysis it can be seen that the results of the study show that the perception of service performance provided by BRT Trans Kota Tangerang has been in line with expectations of 87.3%, while the remaining 12.70% is still not in accordance with the expectations of respondents. The results of the perception Gap analysis with the expectation of having a gap of -0.5 (Not Satisfied). The results of factor analysis show that the most influential and priority factor is the Tangible point 21 dimension with the highest loading factor of 0.885 (Information on bus services to be skipped in the form of visual / audio on the bus is functioning properly).

.

Keywords*: BRT Trans Kota Tangerang, Perception, Expectation of BRT Users, Service Performance, Servqual*

INTRODUCTION

The existence of transportation is intended to facilitate the movement of people or goods to a place, as a support for the running of activities of daily life. Transportation plays an important role in the development of the region related to accessibility which is the ease and ability of an area to be reached by outside parties. According to Andiriansyah (2015) the function of means of transportation "as a way to make it easier for humans or goods to move from one place to another they want to go".

In the sustainable development agenda of 2030 the Sustainable Development Goals (SDGs) consist of 17 Sustainable Development Goals (SDGs) with 169 targets aimed at ending all forms of poverty, combating inequality and overcoming climate change, while ensuring that "nothing is left behind. There are SDGs target where transportation directly contributes to five targets, namely road safety targets (Target 3.6), energy efficiency (target 7.3), sustainable infrastructure (Target 9.1), urban access (Target 11.2) and fossil fuel subsidies (Target 12.3) (Low Sustainable Carbon Transportation 2018).

Urban transportation is specified in Target no. 11.2 namely;

"Local governments are responsible for encouraging the use of public transportation in urban areas in order to improve traffic safety and reduce emissions. Providing a safe, affordable, accessible and sustainable transportation system for all, increasing traffic safety, increasing public transportation, and paying special attention to vulnerable communities, women, children, people with disabilities and the elderly "(United Cities and Local Governments Asia-Pacific 2019).

The government is responsible for making policies to make decisions in realizing public transportation. This is stated in Law No. 22 of 2009 concerning Road Traffic and Transportation (LLAJ), one of the policies in which regulates mass public transportation, and the government guarantees the availability of road-based mass transportation. In this law, it also regulates that public transport service providers must meet "Minimum Service Standards (SPM), which include" security, safety, comfort, affordability, equality and orderliness "".

In the 2013 Global Report on Human Settlements UN-Habitat concluded that public transport must be the highest priority form of motorized transportation. Joan Clos (Deputy Secretary General of UN-Habitat 2013) stated in the

global report that many cities in developing countries could easily reach public transportation, but most of them chose not to use it because they found that public transport safety and security was inadequate (because of sexual abuse or other forms of criminal behavior). This causes people to prefer to use private transportation (motorbike or car) to support their daily activities.

The high level of private vehicle use has resulted in traffic congestion and inadequate quality of public transport services. The government as a stakeholder and responsible for issuing policies must have the right planning in overcoming urban transportation problems. One of the policies implemented by the government in improving quality is by applying the Bus Rapid Transit (BRT) concept as public transportation. This BRT mass transport system has been well-known throughout the world as a cost-effective alternative to urban mass transit investments. According to Cervero (2014) there are successes for cities that adopt BRT as urban public transportation such as Curitiba and Ottawa

After the success of the operation of the concept of BRT public transportation in Jakarta, "Transjakarta" is a public transportation that has attracted many people. This also had a positive impact on the direct border areas with the capital city, such as Tangerang City, which was also one of the cities that implemented the BRT policy as mass transportation to reduce congestion.

In the Tangerang City Transportation Agency 2017 report (Figure 1.1) that there is an increase in the number of private vehicles each year. This shows that the increasing volume of vehicles that are on the road, and will have an impact on traffic congestion on the road. The Tangerang City Government made a BRT mass transportation policy in the hope that it could attract the public to use public transportation, diverting people who use private vehicles to ride public transportation so that it is expected to reduce traffic congestion.

the number of Trans City Tangerang BRT passengers is quiet, and even has a downward trend every month. This trend needs to be studied further so that in the future the Trans City Tangerang BRT program can still be a public transportation that still exists to serve the people of Tangerang City. The initial step taken was to assess the services provided by the Trans City Tangerang BRT to Trans City Tangerang BRT users. Supranto (2006) argues that;

"A 'company' must be able to give satisfaction to 'customers' to be able to compete. Customers must be satisfied because otherwise they will leave the company and become competitors' customers. This will cause a decrease in customers and cause losses.

"Companies" in the context of this case are the government as service providers and "customers" of the community in terms of service users. The government must measure the community satisfaction assessment of BRT users to immediately find out what factors make the BRT user community satisfied and dissatisfied as an evaluation to improve the quality / quality / services provided.

THEORY REVIEW

Parasuraman et.al in Mukarom and Wijaya (2016), factors that determine the quality of SERVQUAL (Service Quality) services, an approach based on a comparison of two main factors, namely consumer perceptions of the services they receive and services that are actually expected / desired. This model has five dimensions, namely:

1. Tangibles, appearance or physical facilities
2. Reliability, the ability to carry out the promised service accurately
3. Responsiveness, willingness to help consumers and provide fast service
4. Assurance, employee ethical knowledge and ability to convey trust and confidentiality
5. Emphathy, care and individual attention that is given to consumers

Furthermore, this study will classify variables and indicators as a measurement tool based on these five servqual dimensions which are related to the perception of the Trans City BRT service in Tangerang. Then it will be used as a questionnaire for Trans City Tangerang BRT service users.

METHODOLOGY

Servqual method

The purpose of servqual is intended to be able to measure the expectations and perceptions (reality) of customers here, namely the Trans City BRT users of Tangerang, as well as the gaps that exist in the service quality model. By referring to the 5 dimensions of service according to Parasuraman et al which are integrated with the Public Transport Service Standards (Director General Decree No. 687 of 2002, Minimum Minimum Service Standard for Mass Transportation of Transportation Minister Regulation No.10 of 2012 and changes in Permenhub No.27 of 2015 and BRT standards ITDP 2016) which consists of:

1. Tangible (Appearance or Physical Facilities)

Aspects that can be seen and touched on are related to bus facilities and supporting facilities such as at bus stops

2. Realibility (Ability to Accurately Promise Services)

In this aspect it aims to show and realize the service according to what has been promised

appropriately.

3. Responsiveness (Willingness to help consumers and provide fast and responsive services)

This aspect is related to the speed of response from service providers in providing services and can capture customer aspirations

4. Assurance (Knowledge of employee ethics and the ability to generate trust and confidence)

This aspect puts forward guarantees about services provided in terms of security, as well as competent resources in providing services that meet standards.

5. Emphaty (Concern and Attention to Customers)

This aspect emphasizes the attitude of service providers to service with friendliness, communication, and understanding the needs of consumers who want.

The sum of the average dimensions of each servqual item will be entered into the formula as follows.

Serqual Formula = Perception (reality) - Hope

- Servqual = 0 (means Value of Satisfied Service)
- Servqual> 0 (means Service Value is Very Satisfied)
- Servqual <0 (means Value of Service Not Satisfied)**Equations**

ANALYSIS OF SERVICE QUALITY FACTORS

In order to answer the 3rd problem formulation, the results of the Main Priority Quality of Service results from the Gap analysis need to be tested using factor analysis to obtain the most dominant (most dominant) factor so that decision making is more targeted, in this case the method used is Confirmatory Factor Analysis (CFA), while the tool used is AMOS software, where using this tool will be known to the recommendations of dominant factors which are the top priority for decision makers to take policy.

Evaluation of the validity of the measurement model can be done by looking at the results of estimating the load factors. A variable is said to have decent validity for its latent construct if the value of the t-factor is greater than the charge of the standard factor ≥ 0.5. While the evaluation of the reliability of the measurement model in CFA-SEM can use Composite Reliability (CR 7 0.7) and Average Variance Extracted (AVE ≥ 0.50). To see where the most dominant factors can be seen from the highest Loading Factor value, the Recapitulation of the results of priority factors can be seen in the following table:

Paper Submission Method and Copyright

Variabel Laten	Variabel Manifes	Validitas Parsial (LF > 0,5=Valid)		Rank	Validitas OverAll (AVE > 0,5=Valid)		Construct Reliability (CR > 0,7)	
		Loading Factors	Ket		AVE	Kesim-pulan	CR	Ket
Faktor Faktor Prioritas Utama Kualitas Layanan	**T3**	**0,694**	**Valid**	**4**	**0,814**	**Valid**	**0,897**	**Reliabel**
	T7	**0,638**	**Valid**	**8**				
	T14	**0,544**	**Valid**	**9**				
	T16	**0,652**	**Valid**	**7**				
	T18	**0,653**	**Valid**	**6**				
	T19	**0,689**	**Valid**	**5**				
	T20	**0,785**	**Valid**	**2**				
	T21	0,868	Valid	1				
	T22	**0,762**	**Valid**	**3**				

Based on the table above, it can be seen that all values of the loading factor partially every factor ≥ 0.50 (Valid / Eligible), as well as the results of OverAll each construct / concept has been declared feasible, ie with AVE value ≥ 0.50 (Valid / Eligible) Thus it can be concluded that the validity of all manifest variables on the latent variable is good. While the results of the reliability calculation show that all values of construct reliability (CR) ≥ 0.70 (reliable), thus it can be concluded that all these latent variables have reliable reliability. In detail, in order to find out the most dominant key factors in contributing to latent constructs are explained as follows.

1. Main Priority Factors The quality of service that is the most dominant rank 1 is T21 (Information on bus services to be passed in the form of visual / audio on the bus works properly) with a factor loading of 0.868.

2. Main Priority Factors The most dominant service quality ranked second is T20 (Supporting facilities and infrastructure for people with special needs available and functioning properly (priority seats, special seats for wheelchairs, slope of the floor and special texture at bus stops)) with loading factor of 0.785.

3. Main Priority Factors The most dominant service quality ranked 3rd is T22 (There is information on the delivery of the arrival time of the bus in the form of visual / audio / brochure that works well) with a loading factor of 0.762.

4. Main Priority Factors The most dominant service quality ranked 4th is T3 (Available security officers at the bus stop) with a factor loading of 0.694.

5. Main Priority Factors The most dominant service quality ranked 5th is T19 (There is information on disruption and disruption of car

travel in the bus stop via the bulletin board) with a factor loading of 0.689.

6. Main Priority Factors The most dominant service quality ranked 6th is T18 (Available bins at bus stops) with a factor loading of 0.653.

7. Main Priority Factors The service quality that is the most dominant ranked 7th is T16 (Room temperature control facilities at the bus stop function well (fan, ventilation)) with a factor loading of 0.652.

8. Main Priority Factor The most dominant service quality ranked 8th is T7 (Available bins on the bus) with a loading factor of 0.638.

9. Main Priority Factors The service quality that is the most dominant ranked 8th is T14 (Stop service information to be passed in the form of visual / audio on the bus works properly) with a factor loading of 0.544.

So that if the decision maker wants to increase the value of Service Quality (X), the statistic recommendation is to prioritize the increase in the value of the most dominant key factor in T21 (Stop service information to be passed in the form of visual / audio on the bus works properly) with the highest factor loading amounting to 0, 868. Broadly speaking, the Analysis of Confirmatory Factor can be seen through the following path diagram.

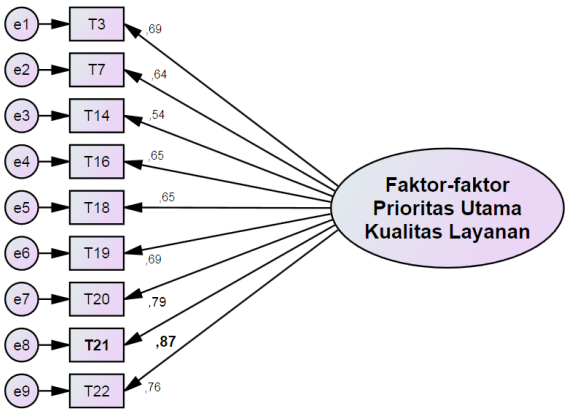

Figure 4.12 Confirmatory Factor Analysis Diagram (CFA)

CONCLUSIONS AND RECOMMENDATIONS

From the results of research on Perception (Perception) with the Expectations of Respondents, the authors can draw conclusions as follows:

1. Research Results show that the average description of respondents' expectations is 3.7, while the Perception average is 3.2, so it can be concluded that the perception of services provided by the Trans Kota Tangerang BRT has been as expected at 87.3%, while The remaining 12.70% is still felt to be less than the respondent's expectations.

2. The results of Gap Analysis show that between Service Perception and Desired Expectations Respondents have a gap that is quite far, with an average of -0.5 (Dissatisfied). The results were caused by all negative Trans City Tangerang BRT service factors, meaning that the Trans City Tangerang BRT Service Perception perceived by respondents was not satisfying the Trans City Tangerang BRT user.

3. The results of Factor Analysis show that if the decision maker wants to increase the value of Service Quality (X), the statistic recommendation is to prioritize the increase in the value of the most dominant key factor in T21 (Information on bus services to be passed in the form of visual / audio on the bus functions with good) with the highest loading factor of 0.885.

Future studies can use qualitative methods to get descriptive results directly in the field that cannot be explained in this study. In addition, in the future, the relevant agencies can work together with academics to survey and interview directly with BRT users. This can help agencies get evaluation reports on work programs in real time. And know what things must be improved in terms of service and that are maintained.

A MULTI-SPATIAL ASSESSMENT FRAMEWORK TO GEOLOGICAL HAZARD FOR HIGH-RISE BUILDING PROJECT IN METRO MANILA, PHILIPPINES

Michael V. Almeid[1] and Andres Winston C. Oreta[2]
[1,2]De La Salle University, Philippines

ABSTRACT

On Metro Manila Earthquake Impact Reduction Study (MMEIRS) conducted from 2002 to 2004 by Japan International Cooperation Agency (JICA) together with the Philippine Institute for Volcanology and Seismology (PHIVOLCS) and the Metro Manila Development Authority (MMDA), a worst-case scenario with a 7.2 earthquake magnitude in Makati, would have structural impacts on 50% of infrastructures from partial to heavy damage, 18.3% would be heavily damaged, 32.8% would be partially damaged, and major lifelines and utilities that provide electricity, telephones, and water could be cut off. There will be 2,300 casualties, 7,700 injuries, and 156,000 displacements. In this study, we model the earthquake risk of high-rise building projects in Global City, located at the eastern portion of Makati City near Marikina Valley Fault System. To accomplish this, we identified important geological hazard-related factors and distributed survey question to experts to gather estimation of the importance of each factors, and Monte Carlo Analytic Hierarchy Process (MCAHP) was used to determine the consistency of the expert's judgment as well as the relative weights of each factor. These factor weights from the MCAHP are applied to the gathered data, and a Quantum GIS software tool was utilized for visualization, producing a geo-hazard map that is color-coded representing weighted-simulation levels of estimated earthquake hazard risks. Such a GIS weighted overlay analysis map will guide city government councils and other stakeholders to prepare or proactively promote appropriate land-use policy that will minimize threat to life and property each time an extreme natural event such as earthquake occurs.

Keywords: Monte Carlo analytic hierarchy process (MCAHP), Geographic information system (GIS), Geological hazard, High-rise building

INTRODUCTION

In a recent survey conducted by Skyscraper center, within the last decade an average of about seven (7) new high-rise buildings every year is completed making the Philippines top ten among countries around the world with the most number of high-rise buildings 150 meters and taller. Metro Manila provides a salient example almost all new buildings, office towers and particularly residential buildings have more than thirty floors as shown in Fig. 1 Progression of High-Rise Buildings in the Philippines.

Moreover, the rapid progression of high-rise building in high seismic areas in Metro Manila has led the greatest risk associated in its development. Geological hazard threaten safety and health of the City residents and its attractiveness of as the preferred residential and business location in the country. Disaster risks have to be carefully assessed so that measures may be introduced to avert potential danger to life and damage to property. In this study, we model the earthquake risk of high-rise building projects located at Makati City.

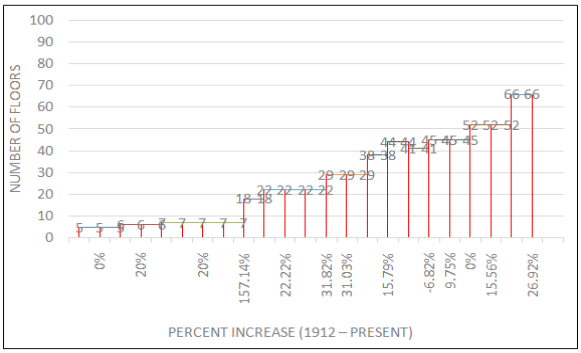

Fig. 1 Progression of High-Rise Buildings in the Philippines. Source: www.skyscraper.com

Makati City is occasionally beset by natural and man-made disasters brought about by geological, meteorological, and technological hazards. The proximity to West Valley Fault System contributes to geologic hazards, notwithstanding the density of high-rise building, infrastructure and technological development in the City.

Makati lies within a tectonically active region in the Philippines known as the Philippine Mobile Belt, and has experienced numerous destructive earthquakes in its recorded history. There are six (6)

known tectonic earthquake generators affecting the area, namely (MGB, 2003 and Daligdig and Besana, 1993): (1) the Valley Fault System, (2) the Philippine Fault Zone, (3) the Lubang Fault, (4) the Casiguran Fault, (5) the Philippine Trench, and the (6) Manila Trench. The nearest active fault within the City is the West Valley Fault.

Based on Metro Manila Earthquake Impact Reduction Study (MMEIRS), a worst-case scenario with a 7.2 earthquake magnitude would have the following impacts in Makati based on 2004 data:

- Structural Impacts: 50% of infrastructures would suffer partial to heavy damage
  - 18.3% (9,200)would be heavily damaged
  - 32.8%(16,500) would be partially damaged
  - Major lifelines and utilities that provide electricity, telephones, and water could be cut off due to seismic activity
- Human Impacts: There will be 0.5% (2,300) casualties, 1.6% (7,700) injuries, and 156,000 displacements.

As shown in Fig. 1, the official trace of the Marikina Valley Fault System can be seen on the eastern portion of Makati City. This fault system cuts across Barangays East Rembo, West Rembo, Comembo, Pembo and Rizal in District II. Earthquakes are part of a natural process and the damage it causes to urbanized areas affects decisions made on where and how to build. Whether these are houses, roads, skyscrapers, malls or any other structure needed for habitation or commerce, the structural system must fit the type of underlying material on which it rests.

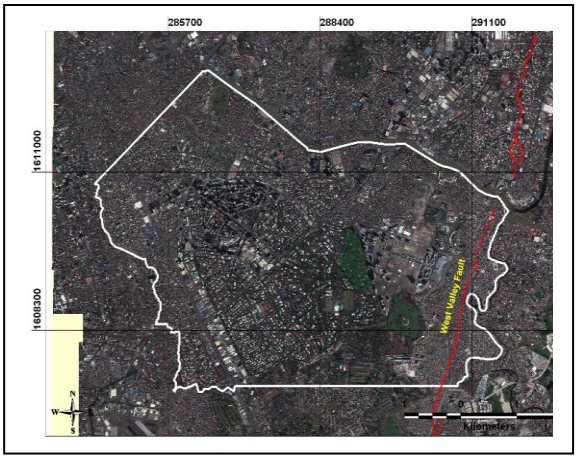

Fig. 1 Trace of the Valley Fault within Makati City. *Source: Philippine Institute of Volcanology and Seismology; Google Earth*

The objective of this study is to determine the importance of the identified earthquake risk factors on a highly urban Central Business District in Metro Manila. Furthermore, this study explores how the Analytic Hierarchy Process (AHP) can be combined with Monte Carlo method and spatial modeling using GIS for vulnerability assessment due to earthquake hazard. AHP is popular as a practical decision making tool applied in different fields. It converge traditional judgments of decision makers to a single numeric preference in order to estimate the pairwise comparisons of all pairs of objectives and decision alternatives while Monte Carlo method is known in testing statistical significance and variation due to uncertainty (Banuelas and Antony, 2004) . This paper proposes the use of both methods to test the statistical significance and variation due to uncertainty of the resultant rankings of earthquake risk factors.

The Analytical Hierarchy Process (AHP) is a decision-aiding method developed by Saaty (Saaty, 2008). It aims at quantifying relative priorities for a given set of alternatives on a ratio scale, based on the judgment of the decision-maker, and stresses the importance of the intuitive judgments of a decision-maker as well as the consistency of the comparison of alternatives in the decision-making process (Saaty, 1980). Since a decision-maker bases judgments on knowledge and experience, then makes decisions accordingly, the AHP approach agrees well with the behavior of a decision-maker. The strength of this approach is that it organizes tangible and intangible factors in a systematic way, and provides a structured yet relatively simple solution to the decision-making problems (Skibniewski and Chao, 1992). In addition, by breaking a problem down in a logical fashion from the large, descending in gradual steps, to the smaller and smaller, one is able to connect, through simple paired comparison judgments, the small to the large (Al-Subhi Al-Harbi, 2001). AHP is MCDM method where the process factors are hierarchically organized. Vertically, objective is on the highest level, with criteria, subcriteria and alternatives on lower levels, respectively, as it is showed on the hierarchical structure on Fig. 2 (Petronijevic et al., 2015).

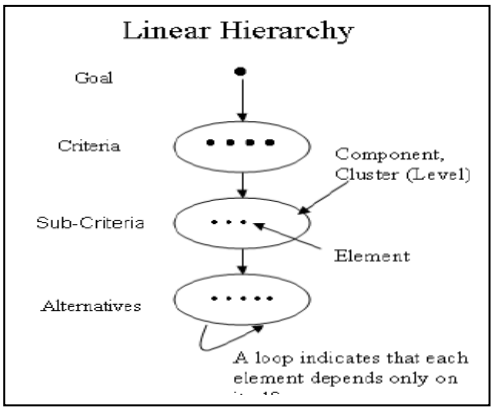

Fig. 2 Hierarchical structure for AHP model

For each level − the criteria, subcriteria and alternatives, elements are compared in pairs. It means that one unfamiliar with the methodology of AHP can compare two elements from the same level according

to verbal description scale. Fundamental scale used to compare the elements consists of verbal judgments ranging from equal to extreme (equal, moderately more, strongly more, very strongly more, extremely more) (Petronijevic et al., 2015). Corresponding to the verbal judgments are the numerical values (1, 3, 5, 7, 9) and intermediate values (2, 6, 8).

Comparison results of n elements belonging to Saaty's scale and AHP hierarchical structure levels are comparison matrices. These matrices ensue vectors priority or $\omega = (\omega 1, \omega 2, \ldots \omega n)^T$, ω is the eigenvector of corresponding matrix. Vector priority involves normalized values which determine importance of the elements – weights of the elements which are compared. This is the method for determination of the priority vector of criteria, the priority vector of alternatives, and as the final result the priority vector of the objective. The priority vector of objective ranks alternatives respect to the importance of the criteria. Judgment consistency ratio (CR) of $CI = (\lambda_{max} - n)/ (n - 1)$, n is the matrix size with the appropriate value in Table 1. If CR is more than 0.10, the judgment matrix is inconsistent (Saaty, 1990).

Table 1 Random consistency index (RI)

n	1	2	3	4	5	6	7	8	9	10
RI	0	0	.58	.90	1.12	1.24	1.32	1.41	1.45	1.49

GIS-multi-criteria evaluation have been used intensively in environmental planning and ecology management. Most analyses within this application area concern land suitability, resources allocation, plan/scenario evaluation, impact assessment and site search/selection problems (Chakhar & Mousseau, 2007). The application of MCDM in general and especially spatial MCDM in the context of geological risk management is still rare. However several methods have previously been employed and developed for vulnerability assessment. Among them, the analytic hierarchy process (AHP) is one of the most commonly used method of assessment (Ying, et al., 2007; Li, et al., 2007), which works on a premise that decision making of complex problems can be handled by structuring the complex problem into a simple and comprehensible hierarchical structure. Li, et al. (2007) utilized the GIS model approach to research the current condition of eco environment quality for typical area of red soil hilly region. Li et al. (2009) established an environmental information system database. Based on the database, an eco-environmental vulnerability assessment method using integrated fuzzy AHP (FAHP) and GIS was developed for the Danjiangkou Reservoir Area. According to eco environmental conditions and entropic effects, vulnerability was classified into five levels: potential, light, medium, heavy and very heavy.

METHODOLOGY

Weighted simulation analysis using MCAHP is applied and integrates with the spatial data in order to describe the causative factors of a phenomenon under concern. The selection of criteria was based on the expert's opinion and availability of data. This overlay was carried out as a Boolean overlay.

In the second phase, Ranking Method was used, where every criterion under consideration was ranked in the order of the decision maker's preference. Each factor was weighted according to the estimated significance. The inverse ranking was applied to these factors. Factor of rank 1 is the least important and 9 is the most important factor. In the third phase, the formula=P($X \leq x$) will be used to draw a random number equal to or greater than 1/9 and not greater than 9 in the Pair-wise Comparison Matrices to test the statistical significance, and variation due to uncertainty of the resultant rankings of each risk factors using Monte Carlo simulation. The simulation of iterations *n* will provide estimates of the probabilities associated with the vector of priorities of the following criteria below:

- Six contributing factors for Earthquake are:

(Q1) Distance from Valley Fault –Areas within 5-meter buffer zone are exposed to ground rupture

(Q2) Alluvial and Rock Material Deposits – Areas with this type of material underneath produces deterministic Possible Ground Acceleration or shaking.

(Q3) Loose sand and Shallow Ground Water Table – Areas with this type of subsurface soil are prone to liquefaction.

(Q4) Very Steep and Unprotected Slopes – Areas of rock slides from towering walls of adobe are susceptible to landslide.

(Q5) Infrastructure Density- Above and underground utilities particularly electrical line and gas pipes may cause fire outbreak.

(Q6) Distance from Sea Coast – Proximity to source of tsunami.

For the Mapping and Table inputs, the CBD barangay maps were then subdivided into equidistant square grids for distance reference using a customized Python Application Programming Interface (API) on Google Maps. Vertical elevation intersections and horizontal boundaries were identified and marked for analytical measurement. For the AHP Expert Judgment portion, a survey Questionnaire was distributed. The data for AHP was gathered, analyzed and tabulated to calculate the weight of each disaster criteria.

RESULTS AND DISCUSSION

Pair-wise comparison matrix is created by assigning weights by experts. The weights are further

evaluated in finding alternatives and estimating associated absolute numbers from 1 to 9 in fundamental scales of the AHP. These weights can be computed automatically in Microsoft Excel. Hence, the results of the relative weights of Q1 = Distance from Valley Fault , Q2 = Alluvial and Rock Material Deposits , Q3 = Loose sand and Shallow Ground Water Table, Q4 = Very Steep and Unprotected Slopes , Q5 = Infrastructure Density and Q6 = Distance from Sea Coast.

The MCAHP computation results reveal that the Very Steep and Unprotected Slopes (Q4) at 31.00% is assessed by experts to be the largest contributing factor for earthquake hazard, followed by (Q2) Alluvial and Rock Material Deposits at 19.00%, (Q3) Loose sand and Shallow Ground Water Table at 16.00%, (Q6) Distance from Sea Coast at 15.00%, (Q1) Distance from Valley Fault at 11.00% and (Q5) Infrastructure Density at 9.00%. The consistency as measured in the in pair-wise comparisons of *C.R.* = 0.014 (value < 0.10) indicates that the basis expert judgment is reasonably consistent.

For the simulated weights, (Q4) Very Steep and Unprotected Slopes at 31.00% to be the largest contributing factor for earthquake hazard as shown in Table 2.

Table 2. Simulated priority weights for earthquake related factors

	Q1	Q2	Q3	Q4	Q5	Q6	Wt	C.R
Q1	1	0.6	0.6	0.3	1.1	0.9	.11	1.4%
Q2	1.7	1	1.8	0.6	1.6	1.0	.19	
Q3	1.7	0.6	1	0.5	2.3	1.1	.16	
Q4	2.9	1.7	2.2	1	3.4	1.8	.31	
Q5	0.9	0.6	0.4	0.3	1	0.7	.09	
Q6	1.1	1.0	0.9	0.6	1.4	1	.15	

Finally, a Geo-hazard map was generated from the integration of criteria weights from MCAHP with the criteria maps into the GIS software. The map presents a rank of highest and lowest suitability areas. The geo-hazard classification is divided into three classes: Low Risk, Moderate Risk and High Risk (see Fig. 3, 4 and 5).

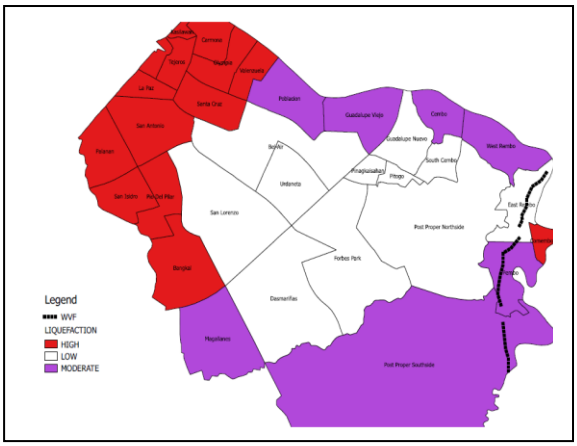

Fig. 4. Makati city urban CBD Earthquake-hazard map (Liquefaction prone areas) using AHP weighted overlay analysis on existing quantum GIS for earthquake.

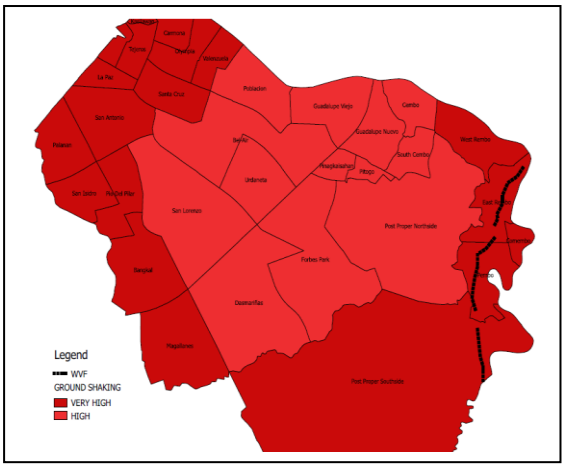

Fig. 5. Makati city urban CBD Earthquake-hazard map (Ground Shaking prone areas) using AHP weighted overlay analysis on existing quantum GIS for earthquake.

CONCLUSIONS

In this study, MCAHP is combined with GIS to come up with a tool for evaluating geological hazards in the CBD areas in Makati City. Such tool was developed after gathering topological information about the city and also reliable (C.R.< 0.10) expert criteria assessment for each earthquake related risk factors, and then applying multi-criteria analysis techniques based on AHP to an open source Quantum GIS software.

The developed tool will be a very valuable resource for consulting, planning agencies and local governments managing risk, land-use zoning, damage estimates, land tax valuation, life and property insurance claim validation, good governance, lifeline emergency services and remediation efforts to mitigate risks. Moreover, the technique applied in this study can easily be extended to other areas, where other factors may be considered, depending on the availability of data.

Provision of more community open spaces as staging areas during disasters and the control of development in identified risk areas are some of the needed land use interventions. Highly-congested, sub-standard housing near the West Valley Fault Zone need some re-blocking to clear the 5-meter easements on both sides of the fault line. Re-blocking will allow for more efficient development of medium rise housing facilities and the conversion of fault zone easements into linear parks. The West Valley Fault Zone traverses the congested barangays in the Eastside Cluster (i.e., Barangays Pembo, Comembo, Rizal, East Rembo) including West Rembo and Post Proper Southside. Barangay Rizal has been identified as the most vulnerable barangay, the presence of the West Valley Fault Zone and its impact such ground rapture, ground shaking, liquefaction and land-slide.

EXTREME HAZE DURING NON-DROUGHT (ENSO) YEARS: ASSESSMENT ON AEROSOLS CHARACTERIZATION OVER PENINSULAR MALAYSIA IN JUNE 2013

Nur Atiqah Aainaa Abd Latiff[1], and Takashi Machimura[2]
[1,2] Division of Sustainable Energy and Environmental Engineering,
Graduate school of Engineering, Osaka University, Japan

ABSTRACT

Population and economic growth over the Southeast Asia region had triggered to the increasing of pollutant that been released by automotive emission, industrial activity or biomass burning. The occurrence of intense haze episodes become severe in every year degrading the surrounding air quality and reduce visibility which may cause economic loses. However, detailed study on the aerosols concentration, source and its properties remain a challenge due to the limitation of in-situ data. Therefore, this study aimed to analyze the aerosols properties over Southern Peninsular Malaysia by utilizing the satellite and ground based remote sensing. Thus, by emphasizing on 2013 intense haze episode, PM10 concentration combine with aerosols from Aerosol Robotic Network (AERONET) data and some environmental parameters, i.e. rainfall, visibility, and hotspot numbers were investigated. Southern Peninsular Malaysia experience a dry and dense condition in June 2013 with highest temperature with less rainfall were recorded. The aerosols concentration and properties through aerosol optical depth (AOD), Angstrom Exponent (AE) parameter and particle size distribution indicate the presence of fine aerosols during the June 2013 haze episode, which is associates with biomass burning aerosols. Meanwhile, the MODIS fire activity data represents more than 3000 hotspots were recorded over Sumatera region. HYSPLIT modeling shows the pollutant substance from biomass burning activity were transported to the study area on 21st of June 2013 from southwest area which mainly from the Sumatera area.

Keywords: Aerosols, Biomass burning, Air quality, ENSO, Malaysia

INTRODUCTION

Anthropogenic pollution from aerosols and trace gases emission contributing a huge impact towards the air quality not only regional basis but also to the global scales [1], [2]. Moreover, a depth knowledge regarding the aerosols characteristic and properties are important to understand more on its impact on the surrounding environment. The aerosols particle concentration, size distribution and pollutant source may differ in temporal and spatial aspect. Generally, the South East Asia had experienced numerous intense polluted condition which due to several factor such as aerosols emission from industries, transportation and burning activities including land clearing for agriculture, open burning, and fossil fuel [3]. This factors inducing the transboundary pollution to occur and affecting the surrounding area. Nevertheless in Malaysia, intense haze episodes that occurs almost every year especially during southwest monsoon season (that prevail from May to September annually) which usually caused by: emission from automotive and industrial area and transboundary pollution (due to biomass burning) [3], [4]. Previous studies on air quality in Peninsular Malaysia shows that intense aerosols loading were taken place mostly in west Peninsular Malaysia which consist of high urbanized areas [3], [4], [5], [6]. In addition, the increasing number of vehicles which causing heavy traffic in the urban area and rapid development industrialization were led to severe pollution especially near the Klang Valley [3], [7]. However, these studies were largely focusing specifically on the urban area with data obtained during field campaigns over specific region. Furthermore, most of the studies previously analyzing on the spatio and temporal characteristic of the aerosols loading which neglecting on the aerosols properties and the pollutant sources. Therefore, a comprehensive study on the aerosol properties and its impacts need to be addressed in order to provide more understanding on atmospheric pollution.

In addition, the Malaysian haze episodes is also associated with the occurrence of inter-annual climatic changes that affecting the dry and wet season in Malaysia. These variations were associated with the El-Nino / Southern Oscillation (ENSO) and the Indian Ocean Dipole (IOD) event which prevail for a longer period [8], [9]. As been recorded in the previous study by [10], intense haze episode in 1997 and 2006 was not only caused by the forest fire and burning activities but also coincided with the El-Nino occurrence which prolonged the dry season in that year. The dry spell condition had induced the fire to start especially at the peatland area which worsened the air quality in Malaysia and neighboring region [9]. However, in June 2013, a non-ENSO year, an intense haze episodes occurred which affecting the

atmosphere in the southern part of Peninsular Malaysia. These intense haze event had caused negative impacts not only to the human's health but also to the tourism, transportation and economic activity to Malaysia and surrounding country [7], [11]. Based on news reported by the British Broadcasting Corporation (BBC), many schools and universities in Johor and Singapore were closed and flight delays due to low visibility during June 2013 [12]. Therefore, these intense haze on non-ENSO year encouraged us to identify the cause and source of the pollution in greater detail.

In addition, less documentation on the aerosols variation and its particle properties were done in Malaysia which may due to the limitation of data availability. In previous studies, the ground-based measurement or in-situ data were used which will provide point data with high accuracy in certain time period, but they have limited spatial coverage [13]. However, in recent years, both satellite and ground-based remote sensing have provided the ability to retrieve aerosol properties over large areas continuously. There are few satellite remote sensing available to provide useful data for aerosol studies such as, MODIS (TERRA and AQUA sensor), Sea-Viewing Wide Field-of-View Sensor (SeaWiFS), and Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observation (CALIPSO) which helps to provide long-term aerosol information with well-calibrated techniques and cloud screening, together with reliable accuracy (i.e. ±0.05 AOD under clear skies and ±0.15 AOD under moderately contaminated atmosphere) over land [13]. Besides that, the existence of Aerosol Robotic Network (AERONET) that introduced by NASA provides the ground based continuous cloud-screened observations of spectral aerosol optical depth (AOD), clouds, and others aerosol information.

Therefore, in this study we utilized the satellite and ground-based measurement for aerosol products, meteorological data and active fire/hotpots information to analyze the aerosols properties and characteristic by emphasizing on 2013 intense haze episode. Air quality data which been acquired from Malaysian Department of Environment (MDOE) and HYSPLIT trajectory model were used to identify the probable aerosols source and its impact towards the Southern Peninsular Malaysia atmosphere during the study period.

MATERIALS AND METHODS

Study Area and Dataset

Malaysia is located at the Southeast Asia which consist of 14 states which separated by the South China Sea into two regions; Peninsular Malaysia and East Malaysia (Sabah and Sarawak). Peninsular Malaysia also called as West Malaysia is a part of Malaysia which lies on the Asia continent and shares the land border with Thailand in the north and with Singapore at the southern part of Peninsular Malaysia. Fast growing economic development in industrial activities and increasing in population had expose this area with numerous atmospheric pollution in recent years. Numerous haze episodes had been recorded since 1980's and become severe in this last 10 years which caused by the transportation emission, land clearing for agriculture and trans boundary smokes from neighboring country [14]. In 2013, peninsular Malaysia had experienced intense haze episodes with the Southern Peninsular Malaysia (Johor, Melacca and Selangor) were adversely affected and the air quality deteriorated to unhealthy level. Hence, this hazardous situation in the Southern Peninsular Malaysia was lead to poor visibility, serious health problem towards the community and disrupt the economic growth.

In order to examine the aerosol variations in Southern Peninsular Malaysia during 2013, four air quality monitoring station located at Johore Baharu, Malacca, Sultan Abd Aziz International Airport (here after SAAIA) and Setiawan were used with the PM10 concentration as the indicator parameter for the aerosols (as shown in Figure 1). Meanwhile, the metrological parameters such as rainfall amount, temperature, wind speed, and visibility were gathered from NOAA's National Climatic Data Center (NCDC). Daily mean composites of wind vector were computed over the Southeast Asia region. In this region, it strategically depicts the tropospheric flow patterns where; it covers Malaysia and other neighboring countries. The maps were constructed from NCEP/NCAR Reanalysis Product developed by NOAA-ESRL9.

Characterization of aerosol properties has been done using the atmospheric radiation data taken from the AERONET station in Singapore as it the nearest AERONET station to the Southern Peninsular Malaysia. AERONET is a ground-based remote sensing instrument that provided by National Aeronautics and Space Administration (NASA). Furthermore, it provides long term, authentic and continuous data for aerosol research that can also be used to validate the satellite retrievals of aerosol properties and comparison with other databases for climate studies. The AERONET Singapore station (1.30° N, 103.77° E) that were used in this study is located at the southern part of the Peninsular Malaysia where it is the nearest AERONET station to our study area. Also, this site is an ideal for monitoring regional pollution events such as transboundary biomass burning emissions, clouds, local anthropogenic emissions and climate variability [15].

In order to understand more about the aerosols properties for this study, we use the daily average Aerosol Optical Depth (AOD) at 500 nm since this specific wavelength represents the visible spectrum,

which is the most relevant to the aerosol measurement during day time [16]. Besides AOD, Ångstrom exponent (AE) and aerosol particle size distribution are also assessed. In order to complement the quantitative assessment, HYSPLIT trajectory model has been applied for Southern Peninsular Malaysia during the entire haze period.

Further analysis on the source of pollution that occurred in 2013 were done with additional data of the active fire and hotspots which was obtained from the Moderate Resolution Imaging Spectroradiometer (MODIS) from the TERRA and AQUA satellite. This MODIS Active Fire Data acquired from the NASA/LANCE – FIRMS website to monitor the distribution of hotspots within the Sumatera area. Only hotspot counts with confidence level higher than 30% were included in this study.

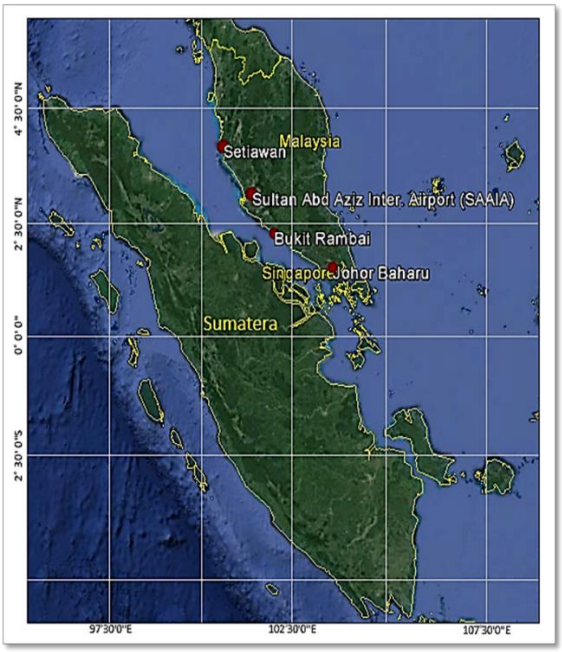

Fig.1 Monitoring stations at the Southern Peninsular Malaysia (Setiawan, Sultan Abdul Aziz International Airport, Bukit Rambai (Malacca) and Johore Baharu)

Methodology

In order to study on the air quality variation during the intense haze during 2013 in Southern Peninsular Malaysia, a quantitative analysis were done for the daily average PM10 concentration and meteorological data (rainfall amount, temperature and wind speed). Then, we identified the period that reached the peak of PM10 concentration and analyzed its relationship with the metrological parameter. Then, the AERONET data (which focusing on AOD, AE, and aerosol particle size distribution) were analyzed to justify the aerosols physical properties. Subsequently, the pollutant source and air masses transportation were tracked by using 5-days trajectories from NOAA HYSPLIT model. Additionally, MODIS Active Fire Data and hotspot count were used as the supporting information for the results acquired from those analysis. Analyzes on the social and economic impact of fire have been done by collecting data and information through secondary data gathered from literature reviews and legal documents.

RESULTS AND DISCUSSION

In general, during the normal conditions, these four stations experiencing the same fluctuation of PM10 concentration level on weekend and weekdays, as shown in Figure 2. These figures represent the weekly variation of PM10 concentration at Setiawan, SAAIA, Malacca and Johor Baharu stations based on daily data recorded from 2000 to 2013. The PM10 concentration were recorded high on weekdays (>40-60 μg m^{-3}), where the concentration level were increased from Monday on to the next day and remain high until Friday. Then, the concentration relatively decreased (<40 μg m^{-3}) during Saturday and Sunday. This was believed to be happened due to automobile emission that occur during weekdays compared to weekend. This situation also had been proved by [3] in previous study which stated that PM10 concentration level keep increasing due to the automobile and industry emissions which classified as anthropogenic causes during normal condition (without haze episodes). The increasing number of car on the road is a major contributor to high PM10 level at these four stations.

However, the PM10 concentration level may vary due to natural annual monsoon changes or inter-annual changes [17]. Trough out the year, Malaysia experiencing dry and wet monsoon season which associate with meteorological factors variation (such as rain rate, wind speed and direction and surface temperature) that causing the fluctuation of PM10 level.

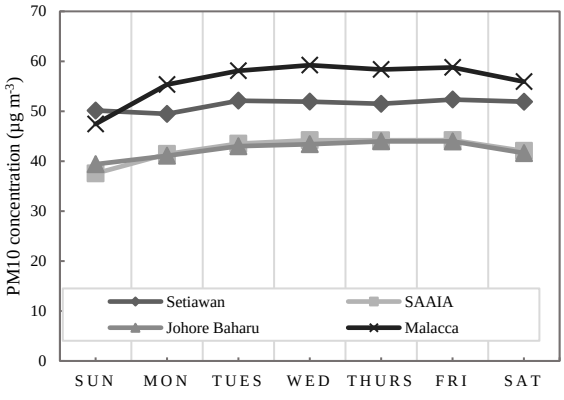

Fig.2 Weekly variation of PM10 concentration at Setiawan, SAAIA, Malacca and Johor Baharu

stations based on daily data recorded from 2000 to 2013

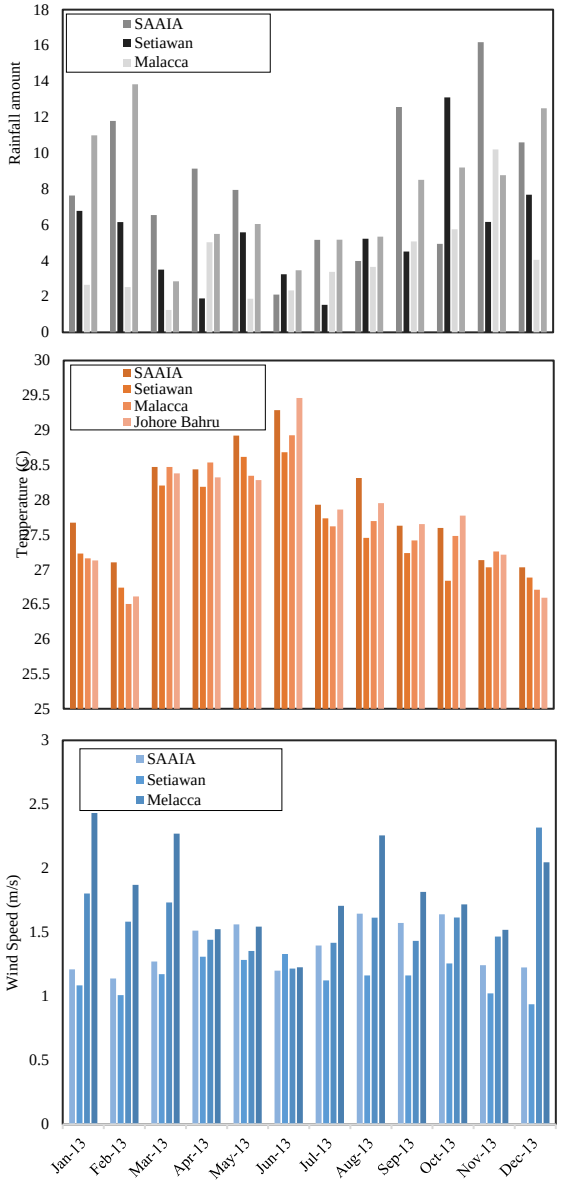

Fig.3 Monthly variation of meteorological parameter which includes (a) rainfall amount, (b) temperature, and (c) wind speed over four stations in Southern Peninsular Malaysia for 2013

Figure 3 presents the monthly meteorological variation which include rainfall amount, wind speed and temperature during 2013 over four stations at the southern part of Peninsular Malaysia. Based on the monthly rainfall amount in Figure 3(a), in the month of June, the rainfall amount for all four stations were recorded low, with the lowest rainfall was at SAAIA station and followed by Malacca, Setiawan and Johore Bahru. This dry condition is also associated high temperature which was observed to be increased in June 2013 as compared to the previous months. Based on Figure 3(b), the highest temperature was recorded at Johore Bahru station (29.46℃) and followed by SAAIA, Malacca, and Setiawan (29.30, 28.92, and 28.68℃). In Figure 3(c) the wind speed variation were started to decrease from April until June, with the lowest wind speed was recorded on June 2013. All four station in Southern Peninsular Malaysia were experienced low wind speed with the average value (less than 1.5 m/s) in June 2013.

These results can be relate with the southwest monsoon season where Malaysia normally experiencing high temperature and low southwesterly wind. These climatic changes are a huge impact toward the aerosols variation and its dispersion. In normal condition, the PM10 concentration tends to be minimal during the northeast monsoon (rainy season) where Malaysia experiences northeasterly winds. While, the PM10 concentration will increase during southwest monsoon, where the region experiences dry season with less rainfall and low level of wind speed (southwesterly winds).

Besides focusing on the seasonal variation of PM10 concentration, inter-annual changes such as ENSO modulations may also amplify the impact of aerosols concentration in Malaysia. In previous studies of intense haze in Southeast Asia, high polluted atmosphere from 1997 until 2007 had associated with dry and low rainfall condition which induced by the ENSO phenomena [18, [19], [20]. During the strongest 1997-1998 ENSO, an intense haze episode were recorded with the PM10 level concentration reached more than 200mg/m3 and been classified in hazardous air condition across the Southeast Asia [20]. In the other hand, 2013 was a year without ENSO yet the Southern Peninsular Malaysia experienced short-term intense haze during June, with increasing level of PM10 concentration and remaining high from 15th to 23rd of June 2013 (MDOE report 2013). By referring to Figure 4, the PM10 concentration level with normal reading (<100 µg/m^3) were recorded in May 2013 and fluctuated until mid-June 2013, where the PM10 concentration trends for all four stations were start to increase until 24th of June 2013. Then, the highest PM_{10} was recorded in the Malacca Station from 21st until 23rd of June (PM_{10} concentration more than 400 µg/m^3). PM_{10} concentration were also recorded high in the other three stations over Southern Peninsular Malaysia which are; Johore Bahru, SAAIA and Setiawan.

Optical and physical properties of aerosols during June 2013 haze episode

In order to explore on the aerosols microphysical and optical properties during haze episode in June 2013 AERONET data from Singapore station were used in this study. Figure 5 shows the daily variation of AOD at 500nm at the AERONET (Singapore Station) during 1st of June until 30th of June 2013. The highest

level of AOD were recorded on 21st of June 2013 with 3.61, and followed by 20th and 22nd June 2013 with the AOD values are 3.16 and 3.01, which indicating the intense level of air pollution happened in this region. The variability in box (b) (Figure 5) representing the normal condition (1st until 2nd of June 2013), which defined as clear condition with the AOD value (< 1.0). Meanwhile, the highest aerosols loading period starting 20th until 23rd of June 2013 recorded over 6 times higher than the AOD value observed on normal day. The increasing of AOD level during 21st of June 2013 significantly shows the presence of large source pollutants to this area.

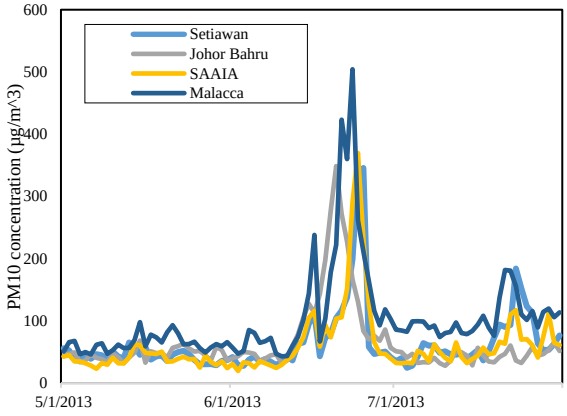

Fig.4 Comparison between daily PM10 concentrations from 1st of May until 31st of July 2013 at the four stations at Southern Peninsular Malaysia.

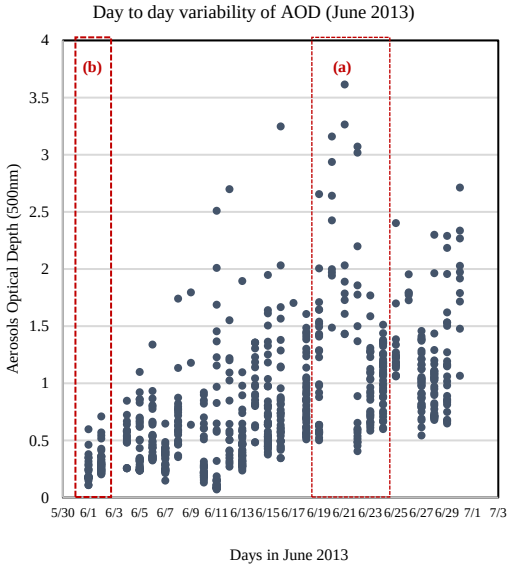

Fig. 5 Daily variability of AERONET derived AOD during haze June 2013.

Aerosol particle's size distribution is one of the parameter that normally being used to distinguish the aerosols particle type [21], [22]. Furthermore, the volume size distribution of aerosols at a certain location is affected by the mixture of different aerosol types. Thus, by referring to this parameter, it is not only provides information on particle size composition, but also describing the pollutant source, its dispersion mechanism, impact on climate system and visibility. In addition, the volume size distribution is characterized by the sum of two lognormal distributions. For each mode, it can be given as follows:

$$dV/d\ \ln\ r = \left(\frac{C_v}{\sigma\sqrt{2\pi}}\right)\exp\left[-\frac{1}{2}\left(\frac{\ln\left(\frac{r}{rv}\right)^2}{\sigma}\right)\right] \qquad (1)$$

Where; $C_v$the columnar concentration of aerosol particles is, σ is the standard deviation, while r refer to the particle radius and rv is the volume mean radius. These algorithm was formulated by [21], which widely being used to derive particle size distributions.

Figure 6 illustrates the available AERONET retrieved aerosols size distribution during June 2013. A bimodal lognormal distribution is observed with fine mode aerosols having radii < 0.7 µm and coarse mode aerosols with radii > 0.7 µm as shown in Figure 6. The occurrence of these two modes of volume size distribution was caused by few reasons. For instance, combination of different air masses with diverse aerosol types [23], homogenous nucleation of heteromolecules into fine mode aerosols or mixed nucleation [24]. It is clearly shown in the Figure 6 that volume concentration for fine mode was increased on 19th until 28th of June 2013 as compared to rest of the days. The fine mode peak value was found within the radius of ~0.26 to 0.33 µm and coarse mode peak value within ~3.86 to 6.64 µm.

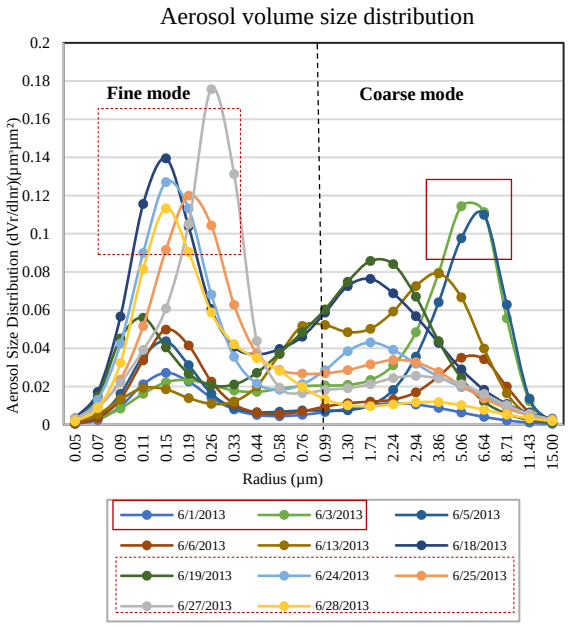

Fig.6 Aerosols size distribution during June 2013 at AERONET Singapore station which describing the size of the pollutant during the intense haze.

The microphysical properties of aerosol are highly relate on their sources. Various techniques have been used to classify aerosol types, and one of the way to do it is with correlation analysis based on Aerosol Optical Depth (AOD) and Angstrom Exponent (AE)(440-870 nm) [25], [26], [27]. These techniques use different threshold to differentiate the types of aerosols. Additionally, the AOD normally represents the level of pollutant during the hazy condition and AE parameter is known as the first derivative (negative slopes) of AOD at specific wavelength which also define the size of aerosol particles. Hence, these two combination of parameter would contribute to a better interpretation of aerosols source classification [15], [16], [28].

The Figure 7 represent the correlation between available AOD (500 nm) and AE (440-870 nm) which been used to classify the dominant aerosol types over study area. This scatterplot shows that there are three different classes presents in this area which been marked as biomass burning, dust or sea salt, and urban or industrial. The AE with value of less than 1 (< 1) indicates that the size of the aerosol is dominated by coarse particles (radius > 2.5 μm) from dust and sea salt, whereas the AE value of more than 1 (> 1) represent the presence of fine aerosol (radius < 2.5 μm) which associated with urban pollution and biomass burning emissions [15], [16], [28]. Aerosol from urban and industrial areas has a higher value of AE with AOD variation based on the level of pollution (concentration of aerosols) in the atmosphere as a result of urban activity. On the other hand, AOD from biomass burning can reach up to 6 in heavy smoke coming from peatland fire [29].

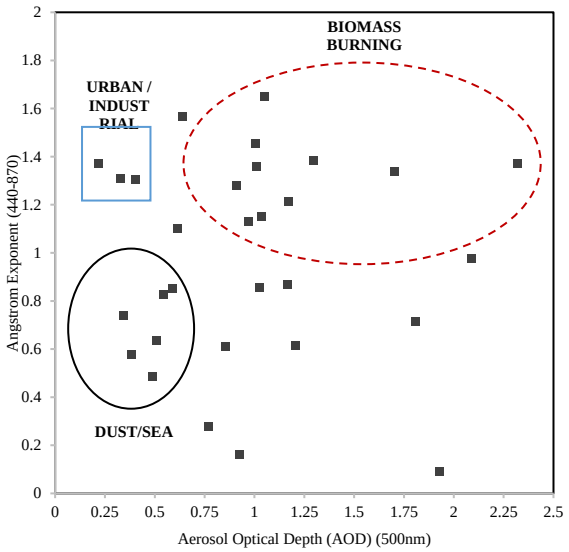

Fig. 7. Scatter plot between Angstrom Exponent (AE) and aerosol optical depth AOD at 500nm over AERONET Singapore station with the classes of different aerosols type.

Higher AOD in the range of 0.8 to 1.3 and AE varies from 1.3 to 1.7 (showed by the dashed line circle) indicates the domination of fine particles during a biomass burning event. Furthermore, this condition occurred when Singapore station experienced air quality degradation as a result of haze based on the AOD level recorded. While, the solid line circle on Figure 7 indicated the existence of coarse aerosol particles with lower AOD variations from 0.25–0.75 and AE values lower than 1.0. This type of aerosol may originate from dust and sea-salt considering this region near to Melacca Strait. Studies by [28] and [30] showed similar result which found dust contamination and sea-salt in Singapore and Kuching (Malaysia) under normal condition.

In order to investigate the possible source locations of pollutant and to examine the dispersion pathways of the air masses before reaching the AERONET station in Singapore, 5 days backward trajectories from NOAA HYSPLIT model was used. As shown in Figure 8, the 5days backward trajectories from HYSPLIT model shows that the polluted substance were transported to the study area from the southwest region and across Sumatera region at lower altitudes.

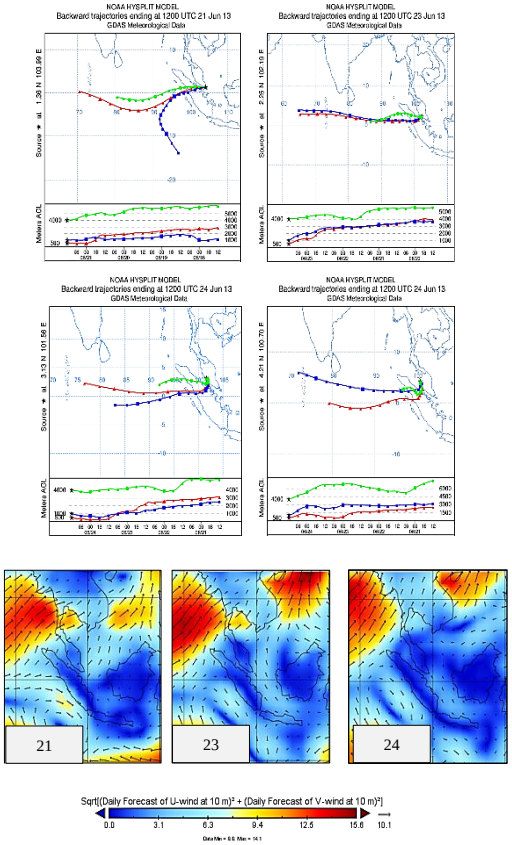

Fig.8. Backward trajectories from NOAA HYSPLIT model for the study area during the highest aerosols loading day (21st – 24th of June 2013) with additional information of the wind speed and direction.

This condition can best be relate with the influenced of Southwest Monsoon that normally occur from June to September which transporting the pollutant particles from biomass burning that originate from the neighboring country to the Peninsular Malaysia and Singapore. It clearly shown in Figure 8, the lower altitude trajectories (500m) were originated from the Sumatera region which may become the high contributors for the intense haze or smokes cover to the Southern Peninsular Malaysia and Singapore atmosphere within 24 hours.

Hence, the wind direction map shows low surface wind over study region on 21st, 22nd and 24th of June 2013. Generally, the southwest monsoon season flow was strengthened by a south to north pressure gradient, with northern hemisphere having a lower surface pressure than southern hemisphere. The pressure gradient is a consequence of the temperature contrast between the northern and southern hemisphere due to seasonal variations. Moreover, the aerosols concentration at Southern Peninsular Malaysia was largely dependent on these direction of the prevailing wind pattern. In which, the southern to southwesterly winds were transporting the pollutant substance towards Southern Peninsular Malaysia and Singapore.

Impact of the biomass burning during June 2013 haze episodes towards the Southern Peninsular Malaysia atmosphere

As been discussed in the previous section, Southern Peninsular Malaysia experiencing a short-period intense haze in June 2013 which dominated with fine particle distributed that were characterized due to biomass burning event that occurred during that period. Once again the PM10 concentration data sets from MDOE over Southern Peninsular Malaysia were plotted together with hotspot count over the Sumatera Island. Figure 9 illustrates the monthly mean fire active data from MODIS Terra and Aqua Satellite over Sumatera, the Fire radiative power (FRP) which defines the rate of electromagnetic energy released by fire was recorded high on June 2013 (with the highest peak of FRP = 484GW) [31]. Daily fire hotspots from MODIS Terra and Aqua satellite shows some high peak had been recorded in Sumatera area during 19th until 25th June 2013. In addition, this peaks correlated with the high PM10 level in Southern Peninsular Malaysia as illustrated in the Figure 9 (b). Respectively, a prominent peak on 19th of June 2013 with more than 3000 hotspot were found over Sumatera, Indonesia which may attributed to the existence of active fire activity that occurred in the Riau Province which had been reported previously. Therefore, biomass burning in surrounding area had indicate on the increasing of PM_{10} concentration in Peninsular Malaysia during June 2013.

These condition can be attributed from the meteorological results in Figure 3, which high temperature and low rainfall during June 2013 had creates a dry condition which may inducing soil moisture loss and led to wild and forest fire occurrences at surrounding region. Meanwhile, low wind speed which inducing less mixing depth promotes a 'stuffy condition' at the Southern Peninsular Malaysia atmosphere which trapped the smokes particle and slow dispersion may happen.

Even though the hotspot count shows some decreasing from 20th of June but it is still considered as higher than the normal days with more than 1500 fire hotspot were detected over Sumatera which related with high PM10 concentration level in all four monitoring station. This condition was caused due to the effect of peatland burning, which it occurs with smoldering combustion and underground fire [32]. Thus, although there is less fire activity or fire hotspots were detected, the emission is still continuously released to the surrounding atmosphere [33]. These results were supported with previous studies that proved the short period haze episodes of 2013 due to peatland burning activities for domestic agriculture and plantation purposes in several provinces in Sumatera [34]. Even tough 2013 was not listed as ENSO year, a similar dry condition as ENSO occurred due to deforestation and land clearing activities that rapidly happen in the Sumatera region [35]. Indirectly, these may increases local temperature, reduced precipitation process and more soil moisture loss; this heightens climatic variability will intensifies drought and influences regional climate [35], [36].

CONCLUSIONS

In this study an effort has been made to analyze the aerosol optical and physical properties during intense haze event in June 2013 over Southern Peninsular Malaysia. Based on the results in Figure 3, the highest AOD value (3.61) was observed on 21st of June 2013 which associated with the intense episode of air pollution that occurred due to large scale crop residue burning in Sumatera region. Plus, the highest peak of daily mean AOD value was six times higher than the AOD value (0.6) observed on clear and normal day. The fine mode volume concentration was found to be more than 1.5 times greater than the coarse mode volume concentration on the high aerosol burden day. While, the scatter-plot between AOD (500 nm) and Angstrom exponent (440-870 nm) showed that biomass burning aerosols were the

dominant aerosol type on the heavy aerosol loading day - 21st to 24th June 2013. NOAA HYSPLIT model of 5 day backward trajectories at different heights were drawn in order to track the pollutant source which been transported to the AERONET station. Figure 7 shows that the polluted substance were transported to the Southern Peninsular Malaysia on 21st of June 2013 were mainly from southwest area and across Sumatera within 24 hours.

In summary, the intense haze episodes in June 2013 was identically characterized by the dominance of fine-sized aerosol that represent as biomass burning pollutant. Besides, MODIS fire activity and hotspot counts over Sumatera region suggested that the existence of transboundary pollution in Southern Peninsular Malaysia and Singapore were caused by biomass burning activities over few province in Sumatera with over 3000 hotspots were detected on 19th of June 2013.

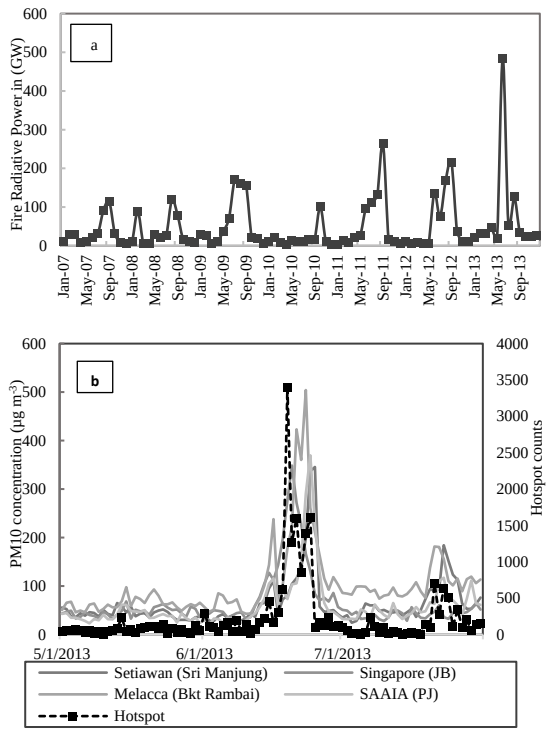

Fig. 9 a) The monthly mean fire active data from MODIS Terra and Aqua Satellite over Sumatera (Jan 2007 until December 2013); and b) Comparison between daily PM10 concentration at the four monitoring stations over Southern Peninsular Malaysia and daily hotspot count over Sumatera.

PEOPLE'S PERCEPTION AND ATTITUDE TO ENVIRONMENTAL POLLUTION AND ITS IMPACTS ON DHAKA CITY, BANGLADESH

Najmun Nahar[1, 2], Zakaria Hossain [1] and Sanjia Mahiuddin[2]
[1]Graduate School of Bioresources, Mie University, Japan,[2]Life and Earth Science, Jagannath University, Bangladesh

ABSTRACT

Dhaka, the capital city of Bangladesh is one of the most polluted cities in the world due to unplanned urbanization, rapid population growth, and resident's irresponsible behavior and attitudes to the environment. Therefore, the study tries to assess the level of people's perception and attitude and also to show the association between people's demographic characteristics with their perception and attitude towards 'Environmental Pollution and Its Impacts' of Dhaka City Corporation as the study area. The study was conducted mainly based on the primary data which were collected through a questionnaire survey, KII and direct observation. Secondary data was collected from various published and unpublished sources. Data were processed from surveyed questionnaire using SPSS software where mean score, percentage, and Standard Deviations were calculated for assessing the level of people's perception and attitude and the Pearson's Chi-square test were done for showing the association between demographic characteristics with the people's perception and attitude. The study results reveal that respondents have a higher level of environmental perception and an environment-friendly attitude in most cases. Age, Education, occupation, and income significantly affect the respondents' environmental perception and attitude exception sex types. It is urgent to change the dweller's environmental behavior for the sustainable environment of this city.

Keywords: Environmental pollution, Environmental Perception, Environmental attitude, Chi-square Test

1. INTRODUCTION

At present, environmental pollution is one of the major global concern in this century [1-2] because it adversely alters the quality of the environment and also affects the human health particularly for developing countries [3-4]. As a developing country, Dhaka, the primate and capital city of Bangladesh is not only the most polluted cities in this country but also the third most polluted city for having the worst level of air pollution [5-6], the second least livable city considering the critical environmental condition [7] and one of the most densely populated cities in the world and more than 15 million people are living in this city [8] with a density of 23,234 people per sq. km. living within a total area of 300 sq. km. [9]. Uncontrolled population growth, rapid urbanization, industrialization, inadequate and improper traffic management and inefficient solid waste management, etc. are the main causes of environmental pollution of this city [10-11].

It is undoubtedly true that our surrounding environment is facing acute problems and most of these problems are the consequences of irresponsible behavior and the attitudes of people on the environment [12] because people's perception and behavior influence their actions through a decision-making process to the environment [13]. Environmental perception and attitude of a person also depend on his demographic characteristics (i.e. age, sex, education, occupation, income, religion, marital status, etc.) and also differs from a community to a community or a country to country [14-15]. For making a better urban environmental management plan, it is important to know people's perception and attitude to environmental components and its quality [16-17] and the people have the right to know and use about environmental information held by public authority who can ensure the availability of environment-related information and can achieve sustainable development through the public response [18]. Therefore, the present study was designed to assess the level of perception and attitude of peoples towards environmental pollutions and its impacts and correspondingly to examine the status of the relationship among the people's perception and attitude with their demographic characteristics of Dhaka City Corporation (DCC) as the study area (Figure 1).

2. METHODS AND MATERIALS

The present study was conducted mainly based on primary data through secondary data were used. For primary data collection, the questionnaire survey, Key Informant Interview (KII) and direct observation were followed. For understanding the people's perception and attitude to environmental

pollution and its impacts on the study area, a semi-structured questionnaire was prepared, checked and then the pilot survey was conducted before questionnaire finalization. In the questionnaire, theme-wise 20 questions were arranged for both people's perception and attitude (positive and negative) related questions and questions pattern were designed according to five-point Likert-Scale where 1= strongly disagree; 2= disagree; 3= undecided/ neutral; 4= agree; 5= strongly agree (Tables 2 and 3). For conducting questionnaire survey conveniently, in total 400 households were selected randomly with 95% confidence level and ±5 precision level [19] from jointly 15,76,746 households from Dhaka City Corporation (DCC) area which is now divided into Dhaka North City Corporation (DNCC) and Dhaka South City Corporation (DSCC) [20-21] where each city corporation has 5 zones (Figure 1) and equally 40 respondents were taken from each zone. The demographic characteristics of the respondents are shown in Table 1. Moreover, 20 KII was done from two city corporations who were engaged in a different responsible position in society. The field survey was carried out from 2nd March to 16th March in 2018 by a research team consisting of 10 surveyors. The sources of secondary data were various published and unpublished documents. All collected data were compiled, processed, statistically analyzed and incorporated in text and tables including frequency, percentages, mean score, and standard deviations; and Chi-square (χ^2) test using SPSS (Statistical Package for the Social Sciences) software Version 23 and MS Excel. ArcGIS Version 10.3 software was used for the preparation of a map of the study area.

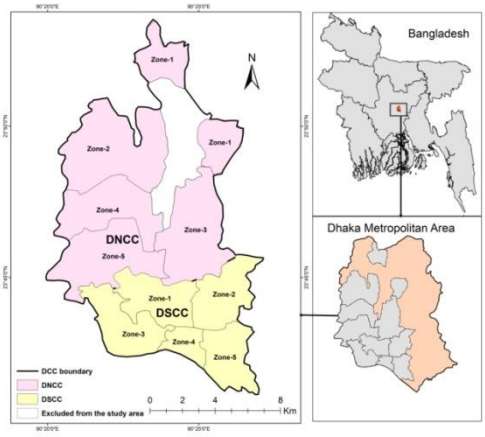

Fig. 1 Location of the Study Area. (Note: Modified from Kabir, 2015)

The level of people's perception and attitude is analyzed by using the mean score and standard deviation from the processed data from the questionnaire survey (Tables 2 and 3). In terms of evaluation of perception, mean score above 3.5 (X>3.5) means the higher level of perception of the respondents; mean scores between above 2.5 and below 3.5 (2.5 >X <3.5) indicates the neutral level and below 2.5 (X<2.5) means the lower level of perception. In terms of evaluation of the attitude level of the respondents in the study area, there is a difference between positive and negative statements for assessing the attitude level of the respondents. In the case of positive statement, score above 3.5 (X >3.5) means the environment friendly attitude of the respondents; mean scores between above 2.5 and below 3.5 (2.5 >X <3.5) indicates the neutral level and below 2.5 (X<2.5) means the not environment friendly attitude but it reverses for the negative statement.

For showing the association between people's perception and attitude with their demographic characteristics in the study area, data were processed from the same questionnaire (Tables 2 and 3) which was also used for assessment of the level of perceptions and attitudes. In this study, 5 independent variables (sex, age, education level, occupation and monthly income) were considered as the vital demographic characteristic of the respondents and used Pearson's Chi-square (χ^2) test to show the significant association among people's perception and attitude and their demographic characteristics about "environmental pollution and its impacts on the study area; where, p>0.05 indicates Non-Significant; p<0.05 is Significant and p<0.01 is Strong Significant [22]. For testing the association among the people's perception and attitude with their demographic characteristics, the formulated hypothesis was *"there will be a statistically significant association between people's perception and attitude with their demographic characteristics (sex, age, education, occupation and monthly income) about environmental pollution and its impacts on the study area".*

Table 1 Demographic Characteristics of the Study Area

Demographic Characteristics		Frequency (n=400)	Percentage
Sex	Male	265	66.3
	Female	135	33.8
Age Group	18-20	6	1.5
	21-30	111	27.8
	31-40	179	44.8
	>40	104	26.0
Education Level	Illiterate	16	4.0
	Primary	48	12.0
	Secondary	151	37.8
	Tertiary	185	46.3
Occupation	Unemployed	27	6.8
	Business	112	28.0
	Service	134	33.5
	Homemaker	74	18.5
	Student	53	13.3
Monthly Income (in BDT)	<10000	133	33.3
	11000-15000	26	6.5
	16000-20000	45	11.3
	21000-30000	110	27.5
	>30000	86	21.5

3. RESULTS AND DISCUSSION

3.1 Assessment of Level of People's Perception and Attitude in The Study Area

From the processed data in Table 2, it is found that people's perception level is high about environmental pollution and its impacts in the study area. If we observe all the data, there is a slight difference among the processed data from 20 questions with 2 themes. In terms of theme "Causes of environmental pollution", the mean scores are found above 3.65 to 4.35 (X>3.5) for the responses against 7 questions (1-7 no.), which means that the perceived level of the respondents is high and they are knowledgeable about the environment of the city. The mean scores are above 3.63 to 4.67 (X>3.5) for the theme "Effects of environmental pollution" which have 13 questions (8-20 no.) which also shows that the perceived level of residents of Dhaka City is also high and they are also informed about the effects of environmental pollution.

In terms of environmental attitude of residents in the study area, from the Table 3, considering the theme "*Negative Attitude to environmental pollution and its impacts*" consisting of 5 questions (1-5 no.), it is observed that the mean scores of the responses against the questions are above 1.86 to 3.34 (X<2.5) for the questions 2-4 no., which shows the environment friendly attitude of the respondents but the mean scores for question no. 1 and 5 are found between above 2.5 and below 3.5 (2.5 >X <3.5), which shows a neutral attitude. The theme "*positive attitude to environmental pollution*" consisting of 6 questions (6-11 no.) and the theme "*Attitude to Initiatives and Legislations for Environmental Management*" consisting of 9 questions (12-20 no.), the mean scores of those questions are 3.54 to 4.36 (X>3.5) which also shows the people's environment friendly attitude; except for question no. 20 which shows a neutral attitude.

Table 2 Level of People's Perception of Environmental Pollution and Its Impacts on the Study Area

Q.N.	Aspects of Evaluation	Strongly Disagree (%)	Disagree (%)	Undecided (%)	Agree (%)	Strongly Agree (%)	Mean Score	S.D.	Perception level
1	Rapid population growth is one of the main reasons for environmental pollution in Dhaka City.	0.0	1.3	9.8	48.8	40.3	4.28	0.68	High
2	Unplanned and ill planned urbanization also proliferate the pollution in this city.	0.0	1.0	10.5	41.3	47.3	4.35	0.70	High
3	Less vegetation has increased pollution in this city.	1.0	8.5	21.0	44.0	25.5	3.85	0.93	High
4	Improper waste disposal contaminates soil, water and air of this city.	1.0	0.0	14.0	52.5	32.5	4.16	0.73	High
5	Industries and Automobiles are the major sources of air and noise pollution.	0.0	1.0	24.3	38.0	36.8	4.11	0.80	High
6	Fossil fuels cause high level air pollution and also contribute to soil contamination and water pollution.	0.0	0.8	50.5	32.0	16.8	3.65	0.76	High
7	Water bodies are contaminated by a variety of chemicals and wastes.	0.0	0.0	11.8	62.5	25.8	4.14	0.59	High
8	Environmental Pollution is a serious problem of urban life.	0.3	0.0	9.5	35.0	55.3	4.45	0.68	High
9	Pollution deteriorates the environmental components adversely and affects the whole environment.	4.3	2.5	10.8	42.3	40.3	4.12	0.99	High
10	Environmental pollution can create a number of environmental hazards.	0.0	0.3	30.3	47.0	22.5	3.92	0.72	High
11	Pollution destroys biota and habitat and leads to the imbalance of ecosystems.	0.0	1.3	21.5	46.0	31.3	4.07	0.75	High
12	Environmental Pollution is harmful to human health and other living species.	0.0	1.0	3.3	23.3	72.5	4.67	0.58	High

EF= Not-Environment Friendly.

3.2 Association Among People's Perception and Attitude with Their Demographic Characteristics

The statistical results (P-value) of the study reveals that people's perception and attitude to environmental pollution and its impacts on the study area are influenced more or less by their five demographic factors (sex, age, educational level, occupation and monthly income). In terms of the environmental perception of the residents in Dhaka City, from Table 4 it is noticed that exception question no. 18, there is no association between people's perception of environmental issues with people's gender types as a vital demographic factor. Considering the different age groups, questions no.1, 2, 4, 6, 11, 13, 15 and 18 show strong association (p<0.01) and question no. 12, 17 and 20 show significant association (p<0.05) with the environmental perception of the respondents in the study area. In terms of educational level, question no.1, 6, 10 and 19 show a strong association and the questions no. 3, 5, 12 and 15 show significant association. In terms of occupation, questions no. 7, 11, and 18 also show a strong association and question no. 15, 16 show significant associations. Moreover, question no. 1, 3, 4, 6, 10, 14, 16 indicates a strong association and question no. 2, 11 and 19 show a significant association between different income groups and the environmental perception of the dwellers in Dhaka City.

Considering the environmental attitude of peoples in the study area, the statistical results notices from Table 5, that only for questions no. 5 shows strong association (0.00<0.01) and question no. 14 and 15 show a significant association (p<0.05) between gender types and the environmental attitude of the respondents. In terms of different age groups, question no. 8, 14, 15 and 19 show strong association and question no.3, 5, 16, 17, 18, and 20 show significant association. In terms of education level, questions no. 1,3, 6-13, 15-16 and 19 show statistically strong association (p<0.01) and question no. 2, 5 and 20 show a significant association. In different occupations, question no. 1, 5, 10-13, 15 and 19 shows the strong association and question no. 2, 8, 9, 16 and 17 show significant associations. Besides, question no. 1, 3, 5, 9-13, 15 and 19 show the strong association and question no. 6, 8, and 18 show a significant association between people's environmental attitudes with their monthly income.

4. CONCLUSIONS

This study attempts to demonstrate the current scenario of the people's environmental perceptions and attitudes toward environmental pollution and its impacts on Dhaka City. The result of the study represents that peoples of different sectors are knowledgeable about environmental pollution and its impacts of the study area but visually the environment of the city is terribly contaminated which means the dwellers of the city do not maintain their environmental behavior and attitude toward this issues and not tried to follow the rules and regulation strictly implemented for protecting environment from different pollution. The outputs of the study strongly support the need for creating awareness among people by providing more environmental education to reduce environmental pollutions and its impacts and also need to make people obliged in following environmental laws for protecting the environment from pollutions. More detailed research about this issue is needed to identify the gaps and associations between people's environmental perceptions and attitudes with their demographic characteristics in the future.

THE CHALLENGE OF DEVELOPING HIGH-SPEED RAIL PROJECTS: RECENT EVIDENCE FROM DEVELOPING COUNTRIES

Aleksander Purba
Engineering Faculty, University of Lampung, Indonesia

ABSTRACT

The plan by Indonesian government to build a high-speed rail (HSR) has previously existed for years. Both the Japanese and Chinese government had both showed interest in the project, and both of them have the technological capacity to build a railway that would connect Jakarta and Bandung. This project was however awarded to China because they made a provision of soft loans for the project, while Japan on the other hand wanted the Indonesian government to completely provide the fund required to execute the project from the beginning to the end of the project. The proposed construction of the railway lines will cut travel time between Jakarta and Bandung from about three hours by car to just 45 minutes only. The project will include integration of the HSR with developments along its corridor through transit oriented developments. The line would attract around 10 million passengers per year in first year of operation, this is because of Jakarta's huge population size in addition to the number of pairs of destinations that the HSR would connect.

Keywords: High-speed rail, Indonesia, Travel time, Ridership, Transit oriented development

INTRODUCTION

A brief history into the railway system in Indonesia showed that the railway transport system was created in mid-19th century when Indonesia was still under the colonial rule of the Dutch. The railway system was created in 1939 so as to facilitate the movement of cargoes and passengers. As at that time, the length of the railway line was 6,324 km long on Java and 1,833 km long on the Sumatera Island. In 2009, the total railway length had fallen substantially from 6,324 km to 3,464 km on Java and 1,833km to 1,350 km on Sumatera Island [1]. The main reason for this decline was the competition of railway transport with road transport, thus more funds were utilized for building more roads at the expense of the railway lines. Hence, Law No. 23/2007 was approved to make railway transport an important means of transportation within Indonesia. This clearly maps out the development guide for the national railway system.

METHODOLOGY: CASE COMPARISONS

Author compare the proposed Jakarta-Bandung HSR corridor with the some of HSR corridors in Asia and Europe regions and to identify key factors that have contributed to its successful. International comparison is especially important in HSR because the research shows important differences across countries due to topography, demographics, nature of transit demand and government investment schemes [2, 3].

EARLY JAPANESE'S PROPOSAL

Japan had already indicated their interest to replicate their Shinkansen HSR technology in Indonesia since 2008. That same year, Japan had displayed their Shinkansen technology and also done a feasibility study. Considering that the Island of Java is identical to the pre-HSR Honshu in Japan, the Japanese government under the Japanese International Cooperation Agency (JICA) therefore proposed the construction of HSR for the Indonesian island of Java, backed by soft loans from the Japanese government, connecting the densely populated capital of Indonesia, Jakarta which suffers from freight and passenger congestion to Surabaya which is about 730 km apart.

A new proposal that focus on building 150 km of HSR from Jakarta to Bandung, which will result in the drastic reduction of the time spent to cover the 150 km from 3 hours to just 45 minutes as shown in Fig.1. Japan which is widely known for the manufacturing of world-class trains was the most favorable to win the contract for construction of HSR from Indonesian government. However, change in government after the 2014 Indonesian gubernatorial election which saw the swearing in of Joko Widodo in October 2014 put an end to this project. The Joko led administration basically the HSR project in January 2015, reason for this action was that the HSR project was quite too expensive for the government to execute and there were several other more important and significant infrastructural projects that were required in the underdeveloped islands outside of Java.

Fig. 1 Japanese proposed route [4]

CHINA'S APPROACH

In 2004, China's State Council adopted the Mid- and Long-Term Plan for railway development and the country decided to venture into the development of HSR. The government proceeded to invest huge sums of money into this plan and, in 2008, it affirmed and upgraded the Plan. Part of China's strategy was the purchase of rail technologies developed countries. This helped to accelerate China's HSR development and led to the development of China's indigenous HSR technology in 2007. This culminated in the manufacture of China's first high-speed train on 1st August, 2008, China vigorously promoted its HSR technology, transitioning and positioning their HSR technology.

Internally, China plans to establish four major train lines, connecting the north to the south and another four lines connecting the east to the west, across the entire length and breadth of the whole country. Externally, several major rail lines are also being planned, one linking Asia and Europe via Russia, another connecting China to Europe via Central Asia and the Middle East, and a third connecting southern China with Indo-China and Southeast Asia [5]. China's HSR strategy has become part an integral belt-and-road strategy and core of China's foreign policy, all these have occurred just within the past decade or thereabout [6]. The 'belt' component comprises of many land routes and the 'road' component on the other hand comprises of many sea routes. This also arise from the fact that both systems of land and sea routes link China to Europe. This initiative also led to the development of special funding and investments [7].

HISTORY AND RECENT DEVELOPMENT

The HSR project was forecasted to cover a distance of about 143 km, linking Jakarta and Bandung, thus becoming Indonesia's first ever HSR project. As highlighted earlier, the Japanese and Chinese government made known their intention. Although the Japanese and Chinese governments had carried out previous comprehensive studies, it was only Japan that went the extra length of issuing a study for a project extending to Surabaya, which was estimate to be about 730 km. This was followed by a counter bid which was submitted by the Chinese government in April 2015, must to the chagrin of the Japanese.

This was followed by a state visit by Joko Widodo, who had a successful meeting with the Chinese president, Xi Jinping on March 26, 2015. After the meeting Xi Jinping publicly announced the support of the Chinese government for the development of Indonesian high-speed project, this was followed by the signing of a memorandum of understanding between the two governments. In July 2015, Indonesia led by Jodo Widodo officially announced their plan to commence the construction of the HSR, this would connect Jakarta and Bandung, the bidding process was then made public, therefore the contest was between the potential bidders which included both the Japanese and Chinese train-makers had. The contest became interesting as the Chinese train-maker organized a Chinese HSR Technology exhibition in August 2015. This was a brilliant move which was not new to either contenders since both the Chinese and Japanese have been engaged in fierce business competition in the past, often using intense lobbying to outdo each other. It was widely acclaimed that the primary reason behind the high display of domineering campaign displayed goes further.

The Chinese government played another card in mid-September 2015, they submitted a new proposal that offered to fully meet the Indonesian government's demands while also eliminating funding required to commence. This was followed closely by several months of bidding, negotiations, between the two countries. It temporarily led to the cancellation of the project, however, the Indonesian government made a decision to select China as the preferred bidder for the US$5 billion project because of its financial structure which was so hard to ignore, considering the fact that this was completely different from what the Japanese plan had proposed.

China's triumph can be alluded to China's willingness fund the project. This would in fact lead to a waiver, which was different from what the Japanese had offered, and the Japanese had also refused to shift their grounds. China had even gone further ahead alleviate its deal by including its commitment to institute a program for the manufacture of light and electric rail system in partnership with local businesses. These products would be targeted at the Indonesian market, and exported neighboring markets, thus creating a seamless technology transfer system that would lead to growth of local technology for renovating and train stations.

Therefore, it looked like Indonesia had benefitted immensely from the Japan-China competition, as the

Indonesian HSR bid earmarked continuous competition between Japan and China in their bid for other infrastructure projects with Asia. The HSR system has 71.63 km of the track on the ground level, while 53.54 km of the track will be raised, and the remaining 15.63 km will be below the surface. This was followed by the groundbreaking ceremony, held on January 21, 2016 to commence the construction of the HSR. The HSR system would be open to the public after its official launch in 2021.

PROJECT'S DESCRIPTION

The HSR is part of the governments' grand ambition of upgrading Indonesia's lagging infrastructure. If successful executed, the project will drastically reduce travel time to just 45 minutes only. The HSR has four stations as seen in Fig. 2.

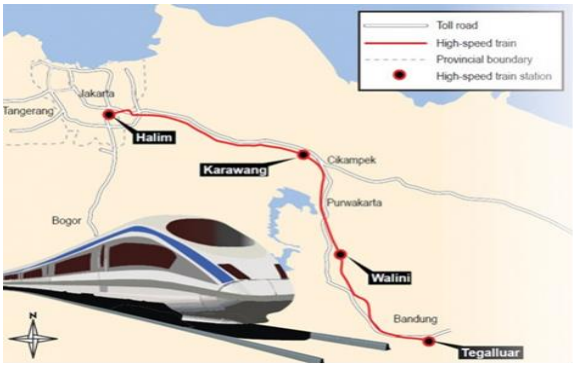

Fig. 2 Route of Jakarta to Bandung HSR

The HSR project will be financed exclusively by China. The project will include integration of the HSR stations with developments along its corridor through transit oriented developments (TOD) [8, 9].

The ambitious proposal for the national railway network comes amid recent news that the cost of the Jakarta-Bandung HSR has swelled to almost US$6 billion, from US$5.2 billion. On the other hand, rail ridership in Indonesia has risen substantially in recent years, making decades of underinvestment and growing urban congestion important considerations for transport stakeholders as they upgrade and construct new lines. Statistics Indonesia (BPS) reports that total rail passengers rose from 199 million in 2011 to 202 million in 2012, 216 million in 2013, 277 million in 2014 and 325 million in 2015. The average length of a passenger journey has simultaneously fallen from 95 km to 68 km, while the country's rail network remains limited to Java and Sumatra, with 22,296 km of total line operational in 2015. The Medium-Term Development Plan 2015-2019 includes an infrastructure development agenda that outlines projects such as having 3,258 km of newly built or rehabilitated rail lines, made up of 2,159 km of intercity railways and 1,099 km of urban railway, and boosting rail cargo volumes to 1.5 million twenty-foot equivalent units annually. Urban rail lines, including a planned light rail transit (LRT) system in Jakarta, are also expected to help reduce congestion and transport costs, which have become the highest in South-east Asia. It was forecast that the new line would attract around 10 million passengers per year in first year of operation, as shown in Fig. 3.

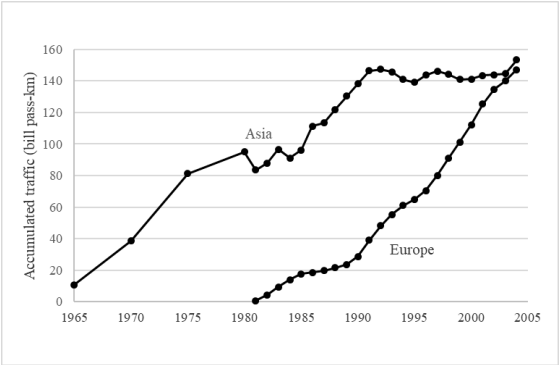

Fig. 3 Accumulated HSR traffic [10]

For 20 years, Shinkansen services in Japan enjoyed a sustained traffic, it gained 100 billion passengers-kilometer. From 1994 to 2004, within the next 20-years interval, the demand halved, because only 50 billion additional passengers-kilometer used HSR. When compared with most European HSR projects which are still in their first 20-year period, it is natural to expect high growth rates as expressed by Fig. 3. Figure 4 shows accumulated traffic used the HSR services in Asia and Europe based on traffic data from each operator during the 2010 to 2016 period. As confirmed by Fig. 4 the only China is still in it incredible constant growth and gained a huge accumulated traffic around 850 billion passenger-km. Two other Asian countries i.e. South Korea and Taiwan started HSR services in first decade of 21 centuries only gained accumulated traffic of 31.4 and 20.2 billion passenger-km respectively during the same period.

Based on long experienced of HSR services in Japan and Europe countries it is easy to predict that most China HSR projects still enjoyed a constant traffic growth for the next two decades most triggering by combined building new dedicated electrified lines and upgrading existing lines. Both South Korea and Taiwan HSR service expressed constant demand growth for the following first decade even the Korea Train Express (KTX) has transported approximately 150 million passengers since the four years after its opening. Taiwan HSR

itself has carried about 100,000 passengers per day for fifty first months of commercial service. However, Shinkansen services is still in its positive growth and gained accumulated traffic of 196 billion passenger-km from 2010 to 2016, two times higher than France figures of 99 billion passenger-km during the same period. France HSR had stagnant traffic growth from 2010 to 2016; in 2016 as an example, SNCF collected accumulated traffic of 49 billion passenger-km, otherwise in 2010 it figures stood at 51 billion passenger-km. Other Europe HSR operators include Dutch, England, and Sweden indicated sustained traffic growth and collected accumulated traffic around 42 billion passenger-km until the end of 2016.

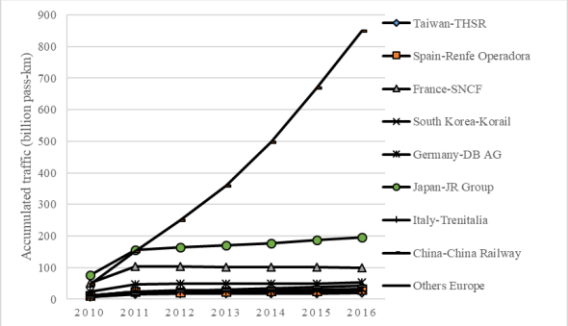

Fig. 4 Accumulated HSR traffic during the 2010 to 2016 period [11]

Based on passenger traffic data obtained from Europe and Asia, the first HSR line constructed in Indonesia is expected to gain considerable amounts of demand. However, it is important to state that in Europe and Asian countries, the construction of HSR lines was as a result of the inability of their conventional lines being unable to meet their demands, thus they needed to add a new capacity to increase rail service. It is also noteworthy to mention that many of these existing rail lines had already been doubled or tripled in a bid to increase the capacity. Therefore, the high demand for conventional rail can be said to have created a market for HSR in these countries. It is inevitable to mention that Indonesia include Jakarta and Bandung lacks of this factor that triggered HSR services successful in Europe and Asian countries.

PROPOSAL OF SG-KL HSR PROJECT

The Malaysian and Singaporean governments signed an agreement on February 2013 that would result in the construction of HSR line, connecting Malaysia [12]. It is of utmost important and key to the successful implementation of Malaysia's national development strategy, (one of the main objective is to increase the country's GDP per person by 150%) by the time this HSR line will be completed in 2020, the Malaysian government is also looking forward to a further boost in the country's economics by closely-tied cooperation with the Singaporean government.

Cost of this project is estimated at RM 40 billion (USD 12 billion). The source(s) of the funding, however, has not been officially disclosed; although some private sources say that Private-Public-Partnership (PPP) funding will be used, others claim that it will be jointly co-funded by both the Malaysian and Singaporean governments considering the fact 335 km of the line will be in Malaysia while the remaining 15 km will be in Singapore. The HSR will have a total of eight stops, seven of which will be within Malaysia and one will be within Jurong East. The high speed rail line which will consist of bullet trains moving at top speed, above an estimated 300 km/hour is projected to become operational in 2026. This would therefore reduce the land journey between Kuala Lumpur and Singapore from about five hours to a mere 90 minutes' journey as shown in Fig. 5.

This project has attracted keen interest from various large corporations within Asia and Europe. However, Mahathir Mohamad who is the current Malaysian Prime Minister had announced on Monday May 28, 2018 that the HSR project will be axed, but he had also explained that it will take some time to execute because the Malaysian government and Singaporean government had also signed a contract on the multi-billion-dollar project. Meanwhile, Dr Mahathir Mohamad, the Malaysian Prime Minister had also assured that the government will remain "business friendly" to all investors involve in the project [13].

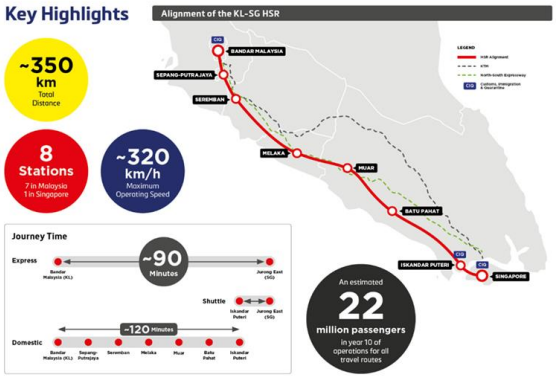

Fig. 5 Proposed Kuala Lumpur – Singapore HSR line [14]

The relationship existing between Malaysia and Singapore is considered unique because of certain factors, these include the geography of both countries, economy, politics, historical background, cultural

heritage, and ethnicity. It is also attributed to the fact that Singapore separated from Malaysia in 1965, hence the similarity. It is also intriguing to know that although both countries have been characterized by healthy competition in economic and social matters, they however enjoy a very high level of economic interdependence as major trading partners. The existing relationship between Singapore and Malaysia has been described as symbiotic. However, this mutually symbiotic as the relationship has been beneficial to both countries, although the relationship has faced some challenges in the past, it has existed since 1965. The Mahathir administration which was in control in Malaysia from 1997 to 2002, was believed by many to be the most stressful period between both Singapore and Malaysia. However, the situation changed after Abdullah Badawi got into power and became the prime minister of Malaysia in 2003, and since then there has been enhanced contact and cooperation between both governments. History is starting to repeat itself again in the part of the SG – KL HSR project [13].

CONCLUSIONS

In conclusion, the Jakarta-Bandung HSR project, linking Jakarta to Bandung was executed by PT Kereta Cepat Indonesia China (KCIC), through mutually agreed business-to-business plan basis, with the Indonesian government. China, which was not only the contender had been awarded the project because of the provision of soft loans for the project; on the other hand, Japan which had showed interest in the project had requested that the Indonesian government funded the project. Surprisingly, Japan was the first to have indicated interested in the project and had even gone ahead to commence working on a feasibility study for HSR track, connecting Jakarta to the country's second largest city, Surabaya, which is about 730 kilometers apart.

Indonesia went further in 2012 to commence another feasibility study focused on the Jakarta-to-Bandung leg, this study was finalized in 2014. The highest operating speed of the trains is estimated at about 350 km/hour, the Jakarta-Bandung high speed rail would result in shortened travel time between the two hubs, reducing the time spent to cover this distance from three hours to 45 minutes only, therefore pushing forward economic development along the line through transit oriented developments. It was projected that the line would also attract about 10 million passengers each year within the first year of operation. This high figure is however a reflection of the densely populated city of Jakarta, and the several number of origin destination pairs that the HSR line would simultaneously serve.

The Kuala Lumpur-Singapore HSR is a strategic project between the Malaysian government and Singaporean government, with its primary goal of facilitating seamless travel between the two capital cities of Kuala Lumpur and Singapore, enhancing business linkages, and connecting the citizens of both countries. The high-speed rail link is expected to reduce the travel time between the two cities from about four to five hours by road to 90 minutes only. However, it is also noteworthy to mention that the surprising decision arrived not long after the newly elected Malaysian prime minister raised the possibility of dropping the project because of its cost implications.

ABSTRACT

Using fly ash (FA; a by-product of coal-based powerplant) as an alternative material to produce concrete might contribute to the reduction of CO_2 emission in the field of general construction. Recent studies have shown that the application of biomineralizing bacteria during concrete production could improve concrete strength. In this research, we aimed to develop a bioconcrete using fly ash as the main binder, and bacteria with $CaCO_3$ precipitation capability to produce concrete micropore filler. In order to do so, we isolated a strain of the bacteria genus *Bacillus* from natto sold in Indonesia, because *Bacillus* are known to precipitate $CaCO_3$ through the production of the carbonic anhydrase enzyme (CA). Next, two types of three variations of FA-mixed concrete (with/without Natto bacteria, with three different ratios of FA/cement), NaOH, and Na_2SiO_3 were prepared, and their compressive strengths measured. We specifically used FA produced by the Suralaya power plant in Indonesia, because of its high percentage of calcium. The results indicated that the durability of concrete specimens made from 100% cement and 100% geopolymer were increased in samples with the natto bacteria added. The presence of bacteria in the specimens was confirmed by SEM, and the presence of $CaCO_3$ precipitates was confirmed by XRD. 16S-rRNA analysis of the bacteria indicated that it is *Bacillus safensis*. A PCR survey using CA specific primers showed that our *B. safensis* strain possesses the *carbonic anhydrase* gene. From these results, we deduced that the specimens containing natto bacteria were stronger probably because $CaCO_3$ produced by the CA-producing bacteria, precipitated and filled the micropores in the concrete specimens.

Keywords: fly ash, concrete, carbonic anhydrase, bioconcrete, CO_2

INTRODUCTION

In recent years, global warming caused by the emission of carbon dioxide (CO_2) from the field of general constructions has caused great concerns. This is because the production of cement, which is the main ingredient of concrete, generates CO_2 in an amount equivalent to that of the produced cement (CO_2/cement = 0.95) [1]. Therefore, reducing the amount of cement might contribute to the reduction of anthropogenic CO_2 emissions. However, rapid economic development in Indonesia has caused the demand for concrete in the country to increase [2].

About half of the power suppliers in Indonesia are thermal power plants. There are more than 100 coal-based thermal power plants in Indonesia, disposing millions of tons of fly ash annually. In Indonesia, fly ash is considered as a hazardous industrial waste. One of the legally accepted methods of treating fly ash is to solidify them into blocks. The blocks were then piled up in a specific "ash yard" inside the power plants.

In recent years, fly ash has been considered as a potential alternative building material. Unlike cement, fly ash is not water-soluble. Therefore, in order to use fly ash as a precursor to produce pozzolan binder, the fly ash is mixed with alkaline solution to form geopolymer paste, which is then used to produce concrete [3][4]. However, such concretes are still in the development stage because in most cases, their strength is weaker than cement-based concrete. Since concrete strength also depends on the presence of micropore fillers, finding methods to fill the micropores in geopolymer concrete might solve this particular problem. Moreover, geopolymer-based concrete was shown to be denser when compared to portland cement-based concrete, and thus has other advantages such as low permeability to chloride ions, which might increase the durability of constructed structures [5].

Current research has focused on the potentials of biomineralizing microbes as agents to produce fillers in concrete [6]. This is carried out by including microorganism-induced calcite precipitate (MICP) agents [6][7], such as the urease-producing micro-organisms into concrete, in order to induce calcium carbonate ($CaCO_3$), precipitations. However, urease-based approach reduces the durability of concrete because urea must be added into the concrete. Urea is known to produce the highly acidic nitrates and nitrites, which could dramatically decrease concrete alkalinity, which in turn might corrode reinforce-ment metals [8].

Another MICP method is by using carbonic anhydrase (CA)-producing microbes [6][9]. Carbonic anhydrase works by catalyzing the inter-conversion between HCO_3^- and CO_2, which might lead to the precipitation of calcium carbonate. This enzyme is known to be present in *Bacillus* bacteria. *Bacillus* is also known to survive in extreme environment, including in alkaline condition [10].

In this study, we focused on carbonic anhydrase-producing *Bacillus* bacteria to induce precipitation of calcium carbonate ($CaCO_3$) as micropore fillers in concrete. We expect carbonate precipitates in the micropores would improve the durability and decrease chloride ion permeability [5]. *Bacillus* species used in this bioconcrete study were isolated from natto in Japan and Indonesia. Meanwhile, the fly ash used in this study was obtained from the Suralaya Power Plant in Indonesia. In order to simplify the experimental system, we used OPC paste and geopolymer paste (with and without bacterial addition) to make test specimens.

MATERIALS AND METHODS

(1) Isolation of natto bacteria

Natto packs were purchased from a supermarket in Surabaya, Indonesia, and from a convenience store in Japan. A quick swab using the platinum loop was done, and then spread over a plate, and cultured overnight at 37ºC. Single colonies were picked and then cultured by shaking in an LB liquid medium overnight at 37ºC. The resulting bacterial solution was spread over an LB plate, and cultured at 37 ºC for 10 hours to obtain single colonies. The single colony was then picked, and again cultured overnight in LB liquid medium, streaked again on LB plate medium, and statically cultured at 37 ° C. for 10 hours to obtain single colony. This operation was repeated 5 times to obtain single natto bacteria. Glycerol stocks of the bacteria deriving from a single colony were made and stored in a -80°C freezer. The following experiments were all performed on cultured samples obtained from the glycerol stocks.

(2) Molecular identification of the natto bacteria

Picked single colony as inoculated in an LB liquid medium and cultured with shaking at 37ºC for 24 hours. Afterward, bacterial cells were precipitated through centrifugation (15,000 rpm, 1 minute). DNA extraction was conducted using the alkaline lysis method following the standard protocol. The 16S-rRNA gene was amplified using the standard PCR protocol for microorganisms using the bacterial universal primers 27F / 1492R [11]. Successfully amplified DNA were then sent to FASMAC Inc. in

Table 2. Compressive Strength at 7 and 28 days (MPa)

Paste	Non Bacteria		*B. safensis*		*B. subtills*

Geo-polymer	45.0	71.8	32.9	77.34	41.2	41.0

Japan for sequencing. Obtained sequences were then used as queries for BLASTn searches on Genbank nr database for species identifications.

(3) Preparation of test specimens

In this study, we used fly ash collected from the Suralaya Power Plant, West Java, Indonesia, as the binder to make specimens. Fly ash from this power plant is classified as class F fly ash [12]. Specimens for comparisons were made from the Ordinary Portland Cement (OPC) as the binder, with the density of 3.14 g/cm^3. The chemical compositions of the fly ash and the OPC are listed in Table 1.

The geopolymer specimens were made by mixing fly ash and alkali activators. Two types of alkali activators, sodium silicate (Na_2SiO_3) and sodium hydroxide (NaOH) were used. The concentration of sodium hydroxide was 8M. Meanwhile, the mass ratio of sodium silicate to sodium hydroxide was kept constant at 2. The mass ratio of binder (the fly ash) and akali was kept at 7:3 to obtain water to solid ratio of 0.23. Specimens made with portland cement were prepared with mixing Ordinary Portland Cement and water with water to cement ratio of 0.23.

The specimens were created with two variations: with and without addition of natto bacteria. Two types of natto bacteria were used: those isolated from natto available in Indonesia, and those isolated from natto sold in Japan. In specimens with bacteria addition, after mixing with a mixer, the bacteria solution was added to the homogenous paste mixture and thoroughly mixed again using a mixer. Concentration of microbial agent in liquid form is 1000 mL/m^3. Afterward, the mix was cast in a cylindrical mold and allowed to set for 24 hours, and

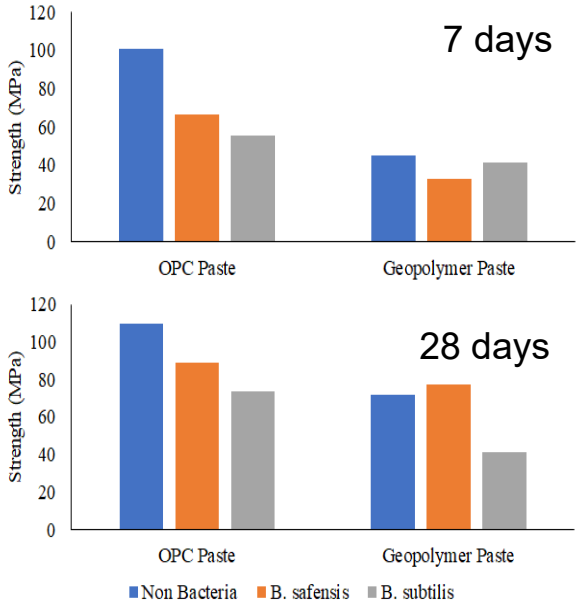

Figure 3. Compressive strength of the specimens at seven days and 28 days.

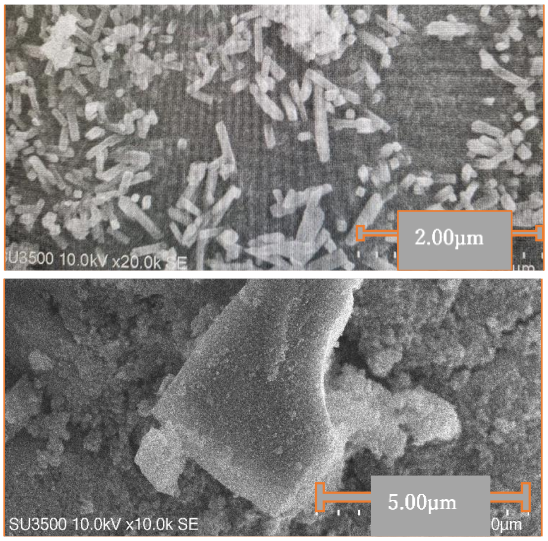

Figure 4. SEM analyses showed the presence of bacterial colony on geopolymer specimens with bacterial addition during production (UPPER). The lower picture showed the absence of any microbe in specimens produced without bacterial addition.

then de-molded and cured in moist condition until the age of seven and 28 days for compressive test. Cylindrical specimens (Figure 1) with a diameter and height of 2 am and 4 cm respectively were prepared for compressive strength test at seven and 28 days according to ASTM C39 (Figure 2) [13]. Microbe-free specimens from both geopolymer and OPC paste were also made as control specimens.

(4) SEM and XRD analysis

SEM analyses were conducted to confirm the presence of bacteria in the specimens. XRD analyses of specimens at the age of 28 days were conducted to confirm the presence of $CaCO_3$ crystals. The analyses were conducted at The Research Center for Nanosciences and Nanotechnology, Bandung Institute of Technology, Indonesia.

(5) PCR exploration to determine the presence of the *carbonic anhydrase* (CA) gene

Amino acid sequences of the CA enzyme from 7 strains of *B. safensis* and 1 strain of *B. subtilis* were downloaded from the UniProt web server [14], and the corresponding nucleotide sequences were downloaded from GenBank. The sequences were used as references to design two sets of CA specific primers we used to do the PCR survey of the *carbonic anhydrase* gene. PCR were conducted following the standard protocol, with the annealing temperatures of 54ºC. Successfully amplified sequences were sent to FASMAC Inc. for sequencings. Obtained sequences were used as queries for BLASTn searches.

RESULTS AND DISCUSSION

(1) Molecular identification of the bacterial species

A 820 base-long sequence was obtained from the 16S-rRNA gene sequencing. For the bacteria isolated from the Japanese natto, BLASTn search using the sequence as the query suggested that the Japanese natto bacteria was *Bacillus subtilis* (*B. subtilis*) with 99% sequence similarity and e-value, 0. Meanwhile, a BLASTn search using the sequence of the Indonesian natto as the query suggested that the bacteria species was *Bacillus safensis* (*B. safensis*) (sequence similarity = 99%, e-value = 0).

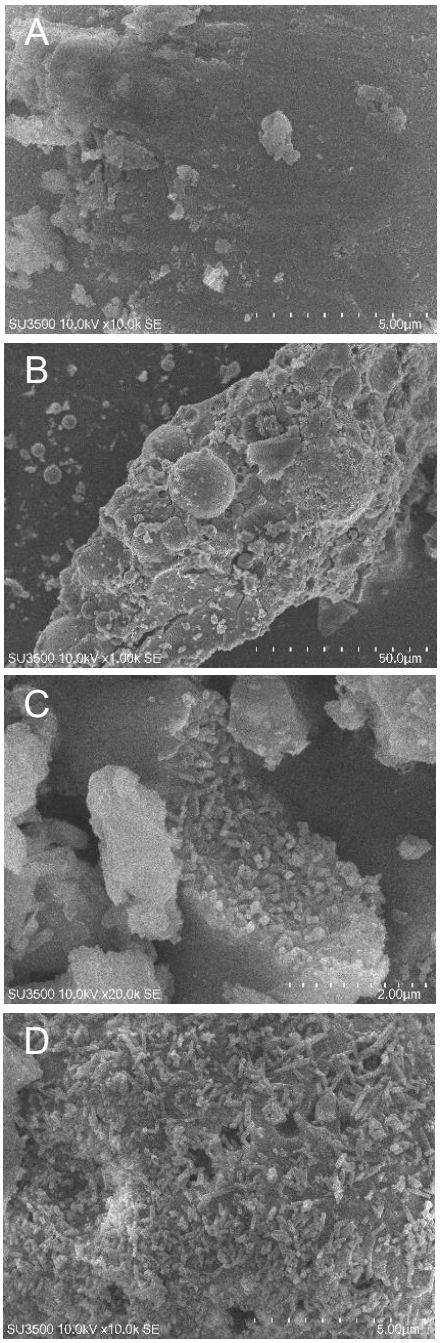

Figure 5. SEM analyses to track the presence of microbes on the specimens.
A. OPC specimen without microbial agent; B. Geopolymer specimen without microbial agent; C. Geopolymer specimen containing *B. subtilis*; D. Geopolymer specimen containing *B. safensis.*

(2) The compressive strength of specimens

Compressive-strength test (Figure 1C) was conducted for bacteria-free specimens, specimens containing *B. safensis*, and specimens containing *B. subtilis*. Average compressive strength was calculated from five identical specimens for each variation. The resulted strength values are shown in Table 2 and Figure 3.

As expected, OPC specimens showed higher strength than the geopolymer ones. This is most likely because, while all particles of cement are water-reactive, the reactivity of geopolymer particles (alumina-silica-based particles) depends on the quality of the fly ash.

The compressive-strength difference was large when specimens containing microbes were compared between those of the age of seven days and those at the age of 28 days (Table 2; Figure 3). This is probably because the specimens did not reach maturity, and thus the strength did not increase to a comparable level on day seven. Therefore, strength comparisons should be performed at the age of 28 days.

Some references suggested using 400–500 ml microbial agent per cubic meter concrete mixture [18][19]. This is roughly only half the amount we used in this study. A comparison between microbe-containing and microbe-free specimens suggested that microbe-free specimens were cured in seven days, while microbe-containing specimens might need more time to cure. This is probably because of the excessive amount of microbes in the mixture acted as CO_2 contributor that did not react with calcium hydroxide in the cement paste.

Our result also indicated that geopolymer specimens containing *B. safensis* showed higher strength compared to those containing *B. subtilis* (Table 2; Figure 3). Our result also indicated that the presence of *B. safensis* might affected the increase in compressive strength to reach the highest value on day 28 (Table 2; Figure 3).

(3) SEM analyses results confirmed the presence and absence of microbes in the specimens

From the Figure 5, we can confirm the presence of 1.00 µm –2.00 µm rod-shaped bacterial particles in the geopolymer specimen containing *B. safensis* (Figure 5C and 5D). This is not seen in specimens without microbes (Figure 5A and 5B). The results also suggested the prominent presence of *B. safensis*

population (Figure 5C), compared to *B. subtilis* (Figure 5D), in the geopolymer specimens. From this observation, we deduced that *B. safensis* probably could survive better than *B. subtilis* in geopolymers, as indicated by the presence of bacterial populations inside the specimen.

(4) XRD analyses to confirm the presence of calcium carbonate

Our compressive strength result indicated that the presence of bacteria increased the strength of geopolymer specimens (Figure 3). If we focused on the ability of *Bacillus* bacteria to produce $CaCO_3$, this could be explained by the possibility that the bacteria precipitated $CaCO_3$, and the precipitates filled the micropores inside the specimens. Figure 6 shows the results of XRD analysis of specimens with and without microbes. The intensity of the peaks indicating mineral presences in Figure 6B (*B. safensis*-containing specimen) is higher that in Figure 6A (microbe-free specimen). Also, the result indicated the presence of aragonite and calcite, crystal aggregates of $CaCO_3$, that could be formed in the presence of living organisms, including CA enzyme-producing bacteria [7][9][20]. This suggests that mineral formation in the geopolymer specimens was probably caused by the presence of *B. safensis*.

(5) The presence of the *carbonic anhydrase* (CA) gene in the bacterial genome

Our survey of the presence of the *carbonic anhydrase* gene in the genomes of the bacteria indicated that both *B. safensis* and *B. subtilis* possess the the gene in question. Sequencings using primers designed to amplify a conserved region of the CA gene of the *Bacillus* family produced 280 base-long sequences from both *Bacillus* (*B. safensis* = sequence similarity = 100%, e-value = 0; *B. subtilis* sequence similarity = 100%, e-value = 1e-138). Although further experiments are still needed for confirmation, we can deduce that both *Bacillus* species have the ability to precipitate $CaCO_3$ using the CA enzyme.

(6) Why the increase in compression strengths can be attributed to bacterial CA

Considering all results together, the increase of compression strengths on geopolymer specimens could be attributed to the presence of *B. safensis*, which, by producing the CA enzyme, precipitated $CaCO_3$ in the micropores of the specimens. We hypothesized the following process to explain this phenomenon. First, water and *B. safensis* were present in the micropores. *B. safensis* releases CO_2 through respiration, filling the micropores with the gas. The CO_2 dissolves in the surrounding water and is catalyzed by the CA enzyme produced by *B. safensis*, forming carbonate ions. The ions then combined with calcium ions abundantly present in the fly ash, forming calcium carbonate ($CaCO_3$) particles. The particles then filled the micropores, and causing the specimens strength to increase.

Our result, and the hypothesis conceived based on the result, presented here, must be further tested. Additional informations about the microbiology of *B. safensis*, the biochemistry and molecular biology of the CA enzyme, as well as informations obtained from further tests on various types of paste and concrete specimens, are still needed. However, we are confident that our progress report presented here contains valuable pieces of information on the development of geopolymer-based alternative construction materials.

ABILITY AND WILLINGNESS TO PAY FOR WASTE WATER MANAGEMENT MAINTENNACE SERVICES (IPAL)

*Marselina Djayasinga and Tsra Subianto

Economic and Business Faculty, University of Lampung, Indonesia

ABSTRACT

Infrastructure sustainability must be maintained through public participation payment for the utilization of these public facilities. However, it is difficult to determine the appropriate tariff of public utilization. Ability and Willingness to Pay (ATP and WTP) are used to get it. This study aims to estimate ATP and WTP of beneficiary of waste water management maintenance services (IPAL). Using a purposive random sampling and cluster technique from 300 RT, there are 153 are selected as samples. There are 3 classification of household: household native inhabitans , household comers without experience with PDAMs, and household comers with experience PDAM. PDAM is another alternative of water supply produced by government. The results of this study are, the highest ATP is household inhabitants compared to the other 2 household categories. The WTP for IPAL is 30% higher than the rate set by the government initially. Increasing WTP is affected by the level of education, reference cognition, level of income and satisfaction. Continuous improvement in technology of water treatmenty, socialization to the community and use of tariffs based on volume of usage must be carried out for the continuity of infrastructure.

Keywords: Willingness to pay, Ability to pay, Waste water management services

INTRODUCTION

Lack of public awareness of waste water treatment has caused some areas to become a crisis of clean water and polluted the environment. Recently, waste water management maintenance services is becoming an important issue in the water protection in Indonesia. According to Hua (2010) the increasing population and reduced water resources have caused the need for clean water to be a very pressing problem in almost all parts of the world and lack of awareness of proper waste water.. This habit is driven by the low charge even free of charge of this services. As a public good, waste water management maintenance services IPAL) in Indonesia, is not on market mechanism. The tariff cannot be determine because no one can express their preference. So, it is needed the method to get the tariff which reflect the ability and willingness to pay of beneficiaries in order to maintenance this public facilities sustain for long time and arose awareness community to protect the water. Community is expected to respond for this public facilities by expected to be willing to participate through pay some cost to maintain the sustainability of this public infrastructure.

Langkapura Baru Sub district, in Bandar Lampung City is one of the worst sanitation areas, where domestic waste water, both black water and gray water, is thrown into the environment without any prior treatment, thus polluting surrounding groundwater and often experiencing drought. Now, the village is being built a Waste Water Treatment Plant, we called IPAL and immediately operating precisely at RT. 05 LK.II Langkapura Baru. The total population of households who will use the service is 350 families.

The IPAL program aims to overcome the problems of clean water and sanitation through the provision of assistance to Low-Income Communities by building communal IPAL. This public facility will treat household black water and gray water waste so that treated wastewater can be returned safely to household and environment in accordance with environmental quality standards. This processed wastewater will be the next source of clean water. The regional government cooperating with the Islamic Development Bank (IDB) only build the IPAL infrastructure, meanwhile for operational and maintenance costs are expected to come from community participation. So that the amount of the tariff is needed to cover this operational and maintenance costs of the IPAL, which will be charged to the community, especially the beneficiaries, which is in accordance with the ATP and WTP beneficiary households

Now, the city government has set a tariff for Communal IPAL in the Langkapura Baru Village for operation and maintenance of this public infrastructure by IDR 100,000 / month / household. This tariff is set by the city government with the consideration that the government will

provide a subsidy of IDR 50,000 / household, and honestly this subsidy can build the same infrastructure in other regions if burden to community. Allen Consulting Group (2003) states that one source of financing for public goods can come from fees in the form of tariffs, where the levy rates are influenced by the ability to pay (Ability to Pay) and Willingness to Pay. Based on this background, it is a technique for estimating tariffs that cover operational and maintenance costs and encourage environmental awareness. One of the methods to estimate is the Ability to Pay (ATP) and Willing to Pay (WTP).

ATP is the ability to pay for public services received based on income that is considered ideal. According to Rubiani (2004), ATP is the amount of money that can be paid by the community to replace the service costs it receives While Russel (1995) states that ATP is a consideration in spending his income / expenditure to buy goods or other services. ATP is related to the limitations of household income, where household need make priorities economically in choosing maximum satisfaction. ATP is the rest of income after deducted by essential expenditure, non-food expenditure, non-essential expenditure.

According [14] one form of participation of community can be seen from their willingness to pay.WTP according to Wedgwood. A (2003) is the maximum amount of an individual's status for willingness to pay for an item or service, Mankiw (2004) defines WTP as the highest price that each beneficiary is willing to pay using the consumer surplus approach of the demand curve . The consumer surplus is the willingness of a person to pay an economic value less the value actually paid by him. Economists, psychologists, and marketing researchers rely on measures of consumers' willingness to pay (WTP) in estimating demand for private and public goods and in designing optimal price schedules [22] and customers pay what they bid (s) so they must bid less than their true WTP if they want to obtain surplus from the transaction.. Using WTP to avoid the problem of free-riders in the determination of tariffs for public goods services [3].

OBJECTIVES

This study aims (1) to calculate the ability and willingness to pay off household to waste water management maintenance services (IPAL) in order to get the tariff in which is resulting which cover operational and maintenance cost and arouse the awareness of households to be more responsible in water protection, (2) to investigate the relationship between respondent’s characteristic with their WTP. This study is expected to provide policy to set tarrif in which keep infrastructure sustainable and community awareness.

LITERATURE REVIEW

Public participation is essential t and may lead to enormous benefits for sustainability development [5, 22] agree that public goods are build by the government should be managed by the community which requires active community involvement. Involvement, participation and some characteristic of household determine their choices in WTP. WTP is a technique to know the willingness of individuals to pay for public goods benefit in which the price of it cannot be determined by market mechanism because of the lack of information or preferences. Some experts also define WTP is the maximum price beneficiaries willing to pay for a given quantity of product or services [21]. WTP as a way of calculating the ability of each individual on an aggregate basis to pay in order to improve environmental conditions to conform to desired standards. Economic valuation is an attempt to provide a quantitative value to goods and services produced by natural resources and environment regardless of whether the market value is available or not [17] and. CVM is done by asking directly to benefit about the value of benefits of public goods includes resources and environment. [12] found that almost 85% of respondents are willing to pay a higher tariff and this WTP is effected by the level of education, family income This result also supported by [11] that the average WTP of consumers on waste treatment services is higher than the tariffs paid.

WTP is based on the user's perception of the public services. To get user perception, it can be used the Contingent Valuation Method (CVM). According to [7] CVM is one technique to analyze the valuation function that can provide qualitative information that is difficult to identify using other conventional valuation techniques. CVM is conducted because people is unable to express its preference for economic, such as for tourism hunting services, dumping tariffs, pollution, waste management, utilizing wildlife, environmental quality, etc. CVM is a method of measuring someone's preference [8]. CVM is measuring WTP by eliciting stated user preferences through direct surveys. The useris directly asked about their WTP by using open-ended questions [17]. In these surveys, household or beneficiaries are offered some alternative services or condition with varying attributes. WTP is inferred indirectly from their ranking or ratings of these alternative services.

Some characteristics of community such as education level, gender, age, lines of class, race,

ethnicity, house type, house distance, income and service quality, awareness, perception and household satisfaction level toward the benefits of public goods in correlating with WTP [4, 13]. Effects on WTP is high when they are interactions with each other.. Community awareness of the environment is influenced by the level of education and knowledge about the environment [7]. According to [17] household concerning will affect WTP and it increases along with improving the quality of services. Income inequalities can influence environmental degradation. Inequalities may affect the overall extent of environmental quality so that the higher income the higher WTP .High level of awareness and knowledge and positive attitude will increase environmental protection [2].

METHODOLOGY

The location of IPAL construction is in the RT. 05 .LK II Langkapura Baru, City of Bandar Lampung. There are 350 households will receive direct benefits from this infrastructure are 350 families. With a quota purposive sampling technique with the cluster method,158 respondents were selected. Through structured questionnaires and interview techniques, to determine the amount of tariff for operational and maintenance services based on their ATP and WTP. The Contingent Valuation Method (CVM) method with game bidding techniques are conducted by giving repeated questions about the desire to pay for wastewater management maintenance services with a number of services. The frequency of water flowed into the household is service scenario. At the starting point, tariffs are used and the service promised by the government is IDR 100,000 / month / RT and water is supplied to household twice a week. The 7 scenarios are designed as follows:

Table 1. 7 Scenarios of Services IPAL

Scenarios	Services	Tariff/ month
Scenario A	Water will be flowed to household once a week	90.000
Scenario B (starting point)	Water will be flowed to household 2 times a week	100.000
Scenario C	Water will be flowed to household 3 times a week	110.000
Scenario D	Water will be flowed to household 4 times h a week	120.000
Scenario E	Water treatment will be flowed 5 times a week	130.000
Scenario F	Water treatment will be flowed times a week	140.000
Scenario G	Water treatment will be flowed every day (7x a week)	150.000

The starting point of IPAL services scenario at B, in which wastewater treatment will be flowed to household 2 times a week with tariff IDR 100.000. IPAL services is decreased or increased by flowing water to household once a week, Increased scenario using IDR 10.000 every stage .If most respondents answer to one scenario selected, then his scenario is the actual WTP desired mostly

Hypothesis Development

To answer the second objective that the relationship between the characteristics of the respondent with their WTP, correlation technique and crosstab analysis techniques are used. The respondent's characteristic consists of 5 elements, namely the number of family members, the level of education, reference cognition. Level of income and satisfaction of the services. The hypothesis developed as follows:

Ha (1):Numbers of Family has a positive correlation with WTP.
Ha (2):Level of education has a positive correlation with their WTP
Ha(3):The reference cognition has a positive relationship with WTP.
Ha(4):Level of income level has a positive relationship with WTP.
Ha(5):The level of satisfaction of respondents has a positive relationship with WTP.

RESULT

Descriptive Respondent

Questioner distributed to 350 households. There are 158 households that returned and responded the questioner or 45%. The purpose of the household classified is to prove the correlation between reference cognition with their WTP. It may be correlated between perceptions of RTs who have no reference at all about clean water management, and households that have already felt

clean water management services such as IPAL, namely PDAM

Table 2. Family Categories of Respondent

Family Categories	KK	Percentage
Household stay formerly	78	49%
Household comers without experience with PDAM service.	43	27%
Household comers with experience with PDAM service.	37	24%

The original RT was obtained by 78 households, namely the RTs that settled in that location and had never moved. During this time they have experience in the difficulty of obtaining water, especially during the dry season. The second is 43 newcomer RT groups, namely RTs who moved to that location and have settled in that location and this household has never experienced water treatment services like the previous PDAM. PDAM is a water treatment service that is managed by the city government where the source of the spring is from a river or mountain or other source, then it is channeled to RT. Third, namely immigrant households that live in that location but already have experience in experiencing PDAM services. They already know a little about the quality of PDAM water, the tariff, the frequency of the water flowing to the previous household. The characteristics of respondents based on the number of family members and the level of education obtained the following results.

Table 3. Descriptive of Respondents

	A	B	C
Family member :			
< 5 person	40 %	65%	60%
≥ 5 person	60%	35%	40%
Level of Education			
< 9 years	40%	20%	15%
9 ≤ x < 12 years	25%	25%	20%
≥ 12 years	35%	55%	65%

Note: A is household stay formerly and never move to other location, B is household comers without PDAM service experience, C is household comers with PDAM experience

Households which stay formerly in that location have a greater number of family members than household comers with relatively lower levels of education than comers. On the other hand, household comers is dominated by small family . They have a family members less than 5 people, but they have with a relatively higher level of education than formerly household.

ATP dan WTP

The Ability to Pay for household stay formerly on average, is lower than to ATP in household comers, but their willingness to pay (WTP) is highest than to the other 2 categories of households. This is presumably because the former households have experience having difficulty obtaining water so they highly value water and realize how difficult it is to obtain clean water. While ATP for household comers with experience using PDAM services is the highest compared to the other two household categories, but they have the lowest WTP compared to the other two household categories. Household comers with PDAM experience have had references to the quality and quantity of clean water provided by the city government so far with cheaper rates because PDAM tariffs have been subsidized by the government.

Table 4. ATP and WTP IPAL (IDR ,000)

Family Category	ATP	WTP
Household stay formerly	295	125
Household comers without experience with PDAM	305	115
Household comers with experience with PDAM	315	95

Based on the questionnaire, the average tariff for PDAM water services, ranges from IDR 100,000 - 300,000 / month with water can be used not only for bathing and MCK but for drinking and cooking. Household comers consider that wastewater management from IPAL are still unsure about the quality of water produced This condition happen because of the source of wastewater from IPAL is come from black and gray water. Whether it is hygienic or not to be consumed, the use of waste water that has been processed by IPAL is still bog question. Based on the IPAL experience, water is usage only limited for non-eating, drinking purposes such as washing clothes, flush for toilet, washing vehicles, flushing plants. Household who stay formerly do not really care about wastewater quality. The important for them is, that water supply is always there regularly every day. For this condition and they want to pay higher because of the benefits of water and water difficulties so far.

WTP

Of the 158 respondents who were filled with the questionnaire, respondents were dominantly chosen scenario F, by 35,7%. They desired the wastewater management services working 6 times a week to flow the water. They agreed to pay IDR140.000 charged per month. If it compares with government tariff which is IDR 100.000, this WTP can increases 40%. A total of 31,4 % of respondents are willing to pay IDR 110.000 or scenario D, in which wastewater treatment is flowed to the household by four times a week, A, B, C, E, F. The respondent's choice is shown in

Table 5. Validity of WTP of IPAL (IDR)

Scenario	Tarif WTP	Valid (%)
A	90.000	10,5%
B	100.000	26,3%
C	110.000	30,8%
D	120.000	31,4%
E	130.000	24,2%
F	140.000	35,7 %
G	150.000	20,8%

The actual WTP is that it is willing to pay IDR 140,000 a month or increase 40% as long as the quality of water treatment is improved, by increasing the flow of water to household 6 times a day. This result is higher than what [7] found in WTP of water supply in Nigeria. It 's mean that the WTP can be pushed to increase if their satisfaction of public services is increased.

Correlation Between the Characteristics of Respondent with Their WTP of IPAL

The relationship of some characteristics of respondents with their WTP used Pearson Product Moment Test. Characteristics of respondents consist of 5 elements, namely family members, the level of education, reference recognition, the level of income and satisfaction. The result on

Correlation Between the Characteristics of Respondent with Their WTP of IPAL

Relationship of some characteristics of respondents with WTP used Pearson Product Moment Test. Characteristics of respondents consist of 5 elements, namely family members, the level of education, reference recognition, the level of income and satisfaction. The result on

Table 6. Correlation Between Characteristics of Respondents with Their WTP

Characteristic Respondent	coefficient	Sign
The family member	0,593	0,230
Level Education	0,786	0,036*
Reference Cognition	0,155	0,025*
Level of Income	0,733	0.090**
Level of Satisfaction	0,740	0.010*

*) significant on 95%
**) significant on 0,1%

From 5 characteristics of respondent, only the family members has no correlation with their WTP of IPAL, others such as level of education, level of income, reference cognition and satisfaction of IPAL services have correlation positively. The more the number of families is not relevant to the more their WTP. The family members has no correlation with WTP because IPAL tariff setting initially, is fixed cost, does not depend on the number of usage. Wastewater treatment by IPAL is not equipped with a meter or water volume meter distributed such PDAM's did. Increasing WTP is also supported by level of education and awareness of wastewater treatment with coefficient correlation equal to 78,6%. The higher level of education, the higher their WTP of IPAL. With higher levels of education and knowledge, household tend to wish and better understand about water protection. The more knowledge about environmental, the higher their WTP. Respondents who have good knowledge about the benefits and damage of the environment, they will tend to be more likely to be willing to pay [15]. Level of income is also correlated with WTP with 73.3%. It means that if the household has more income, the family has more WTP, with a coefficient correlation of 56.8%.

Reference cognition is used as a variable because of past experiences either satisfied or un satisfied of the services, has a big influence on their WTP. For formerly household who often difficult to get clean water especially in the dry season, they have highest appreciate with wastewater treatment, whatever its form. He [6] shows that experience is positively correlated

with environmental awareness. People who have environmental experiences are willing to pay higher. Respondents will have more knowledge that will not be environmentally damaging and are likely to be willing to make conservation efforts environment.

Level satisfaction of household from IPAL services, affects their WTP. Comers households who had experienced the benefits of other water sources, especially those provided by the government, such as the PDAM, The satisfaction of household increases if the quality of water treatment by implementing new technology will increase the quality of wastewater treatment. He [10] shows that more services are added, more WTP increases. Management service in Kampala City, Uganda can be improved by improving the quality of waste services [3].

Level of income does not have a significant effect with degree of freedom 5%, but significant on its 10%. For households, water is a vital goods, requirement and is determined by the government in a fixed rate. So whatever the tariff is charged to household, it will still to pays it unaffected by its income.

CONCLUSIONS

(1) The ATP of household which stay formerly on the location, , on average is lower than others the ATP from other household classification, but their WTP is relatively higher than the 2 other categories of households, because they highly value water and know how difficult it is to obtain clean water when dry season arrives;
(2) The average ATP of household comers who have never had the experience of using PDAM services is relatively highest compared to the other two categories of household, but on average, their WTPs are medium, because they feel the importance of water and feel the quality of wastewater quality treats IPAL is quality standard;
(3) Household comers that have had experience using PDAM services, their ATP is medium, but their WTP are lowest, compared to 2 sample categories of household. They have had experience enjoying water supplied by the government that has better quality and this household is still unsure, is the quality of wastewater of IPAL to be supplied is high such as PDAM did;
(4) Reference cognitive is positively correlated with their WTP because previous references are mainly on experiences with PDAMs with better quality and with tariffs so far;
(5) The city government needs to improve continually wastewater treatment by IPAL using high technology so that the quality of wastewater is quality standards, at least the same with other drinking water and government promote it;
(6) Tariff per household, should be determination as a variable costs or a number of uses.

ABSTRACT

Application of sewage sludge rich in organic matter and nutrients such as nitrogen, phosphorus and potassium tends to improve crop yields. Nevertheless, this use is limited because of their heavy metal content. The objective of this work is to study the effect of sewage sludge on the accumulation of metallic trace elements in seeds and rapeseed oil. For this purpose, two different types of sludge by their metal composition were tested. Compared to the control, the supply of industrial sludge increases the metallic load of seeds and rapeseed oil. This increase is noted with the highest doses 50 and 100 t/ha. The same trend was observed during the two years of application. This effect is due to the richness of these slurries in chrome, cadmium and lead. This modification of the metal composition was accompanied by the decrease in the oil content. Analysis of the fatty acid composition of total lipids shows an increase in the percentage of oleic acid at the expense of linoleic and linolenic acids. On the other hand, the increase of 18: 1 at the expense of linoleic and linolenic acids may be the result of metal-induced alteration. For urban sludge, we noticed a variation in Cr, Co, Cu, Ni and Zn contents in the seeds depending on the doses. However, for Cd and Pb no variation was recorded. An increase in metal trace element levels was well reported at the seed level during the second amendment. We also detected a decrease in oil content with the contribution of industrial sludge. The composition of the total lipids in fatty acids shows an increase in the percentage of oleic acid (C18: 1) at the expense of linoleic (C18: 2) and linolenic (C18: 3) acids under the effect of heavy metals brought by the industrial sludge while no difference is recorded with urban sludge regardless of the dose. No significant differences in heavy metals were observed with the addition of the different doses of urban sludge even after two years of application. Urban sludge has no effect on oil content or fatty acid composition. However, we detected increases in most heavy metals, especially for high doses of industrial sewage sludge.

Keywords: Rapeseed Oil, Industrial Sludge, Urban Sludge, linoleic acids, Metallic Trace Elements.

INTRODUCTION

Rapeseed crop has in recent years a renewed interest in the world for the production of oil, for human consumption and as biofuels besides its use in the feed of cattle in the form of cake. The introduction of rapeseed farming in Tunisia is essentially aimed at increasing the production of oil for human consumption and that of oilseed meal (by-product of rapeseed) rich in proteins sought for animal feed [1]. Despite the adaptation of this crop and the place it occupies in cereal rotation, it is not well developed in Tunisia. The Pactol variety has been recommended for large-scale cultivation in the north of the country where the rainfall exceeds 400 millimeters per year. Rapeseed is also a model plant for phytoremediation. It is known for its ability to extract and accumulate toxic metals [2].

In addition to the nutrients, the residual sludge contains heavy metals, which is one of the repelling factors of their agricultural reuse [3], [4]. The presence of these elements in cultivated soils poses health safety problems because of their possible passage into plants consumed by humans and animals [5], [6].

Numerous studies have tested the accumulative potential of rapeseed [7]-[9] and its effectiveness on some heavily contaminated surfaces with many physiological and morphological advantages [10]. It is for this reason that we chose it to study the effect of sewage sludge especially on the chemical composition of the seeds and the quality of the oil. Few studies have been undertaken in this direction.

For this purpose, two types of sludge (industrial and urban) different in their composition of metals were tested to highlight the impact of heavy metals present in sewage sludge on certain physiological and biochemical parameters of rapeseeds.

MATERIALS AND METHODS

Culture conditions

The test device is installed in the open field at the Oued Souhil - Nabeul Agricultural Experiment Station, located about 60 km from Tunis. For each

type of sludge, 4 doses (5, 25, 50 and 100 t / ha) were put into play and compared to a control without any input. The trial comprising 9 treatments is conducted in four randomized blocks. The semi rapeseed (Brassica napus L.) Pactol variety was carried out in December with a density of 50 seeds/m² and a spacing of 40 cm from which 13 rows per colza plot were obtained.

The rape crop was conducted in two successive seasons, each time; sewage sludge was applied in the prescribed doses before sowing. However, during the second year, each plot was divided in two, the first part received sludge while the second part received nothing. This division was carried out to study the cumulative effect and the aftereffect of the sludge.

Characteristics of the spread sewage sludge

The chemical analysis of Korba's urban sludge (Table 1) showed that iron and zinc are the most represented elements. The average contents found are organized according to the following sequence: Fe >> Zn> Cu> Cr> Pb> Ni> Co> Cd. As for Bou Bouboub Industrial Sludge's (Table 1), they have very high levels of Cr, Pb and Cd. The sequence found is Cr >>> Pb >> Zn> Cd> Cu> Ni> Co.

Pb	54.9	63.3	2854.1	3175.9
Zn	463.2	506.9	821.8	698.5

Analysis method

Oil analysis

Seed oil extraction is carried out by the Soxhlet method [11]. A sample of milled rapeseeds is placed in a cellulose cartridge in the extractor which is connected on the one hand to a ball cooler and on the other hand to a flask containing 100 ml of hexane, pumice and a pinch of anhydrous sodium sulfate. The solvent is boiled using a regulated flask heater. The solvent vapors are condensed in the refrigerant and impregnate the sample placed in the cartridge thus extracting the oil. The appropriate time for the extraction used to obtain a better oil yield is 6 hours. The oil content (OC) expressed in% is given by the following formula:

$$\% \text{ oil} = (m/w) * 100$$

(m: mass of the oil; w: weight of the sample)

Oil yield (OYH) per hectare is determined by multiplying the seed yield (SY) by the oil content (OC)

$$OYH\ (qx/ha) = SY\ (qx/ha) * OC/100$$

The analysis of the fatty acids is carried out by gas chromatography after their conversion into more volatile compounds: the methyl esters. For this we use hot methylation using a methanolic solution of sodium methoxide followed by esterification in an acid medium [12]. The methyl esters thus prepared are analyzed by gas chromatography on a capillary column. Fatty acids are identified according to their retention times. Their rate is determined by the ratio between the area of the corresponding peaks and the sum of the peak areas of all the fatty acids [13] according to the formula:

$$\% \text{ Fatty acids} = (S / \Sigma S) * 100$$

The detection of metal trace elements in the oil is determined by the ICP-AES (Inductively coupled plasma atomic emission spectroscopy) technique. A mixture of rapeseed oil and 10% nitric acid is stirred and then centrifuged at 2800 rpm for 10 minutes. The assay is performed on the lower aqueous layer [14].

Chemical Analysis of Sewage Sludge

For sewage sludge and soil, the pH is measured by potentiation in 1 M KCl after 24 h in the water/soil ratio of 5. The organic carbon was determined by the method of [15]. Total nitrogen (N_t) was determined by the Kjeldahl method. For trace elements, soil and sludge samples were digested with a mixture of HCl/HNO_3 [16] and total concentrations were determined by plasma flash emission spectroscopy (ICP-OES). The apparatus used is of the HORIBA Jobin Yvon type.

Determination of metallic trace elements in seeds

The parched seeds were crushed into powder using a porcelain mortar and pestle to obtain a fine powder. Digestion is done hot with aqua regia. Then, the contents of heavy metals were determined by plasma emission spectroscopy (ICP-OES).

Statistical analysis

All data were subjected to an analysis of variance. The comparison of the means with the threshold of 5% of significance was carried out by the Newman-Keuls test using the Statistica 7 software.

RESULTS

Effect of sewage sludge on rapeseed grain production

The results obtained during the two test campaigns showed that the sludge used as fertilizer improves the production of rapeseed whatever the type of sludge. The increases observed are all the greater as the sludge dose is higher and the lower production is recorded with the treatment without sludge. However, these increases are less important in the presence of industrial sludge compared to urban sludge or a difference of 39.41% for the same sludge input 100t/ha. In addition, the cumulative sludge inflow (2nd spreading) gave less pronounced improvements than those obtained during the 1st spreading. It is important to note that the increase in grain production is due to an increase in the number of seeds and not to an improvement in the weight of the seed. Indeed, the weight of one thousand grains (Table 2) did not undergo any sludge effect in the presence of the 1st application and decreased slightly with the cumulated application. As for the after effect, we note that regardless of the type of mud brought during the previous year, treatments that had previously received sludge gave better yields than those of the control treatment without any input. This is very clear for the 50 and 100t / ha doses. This result can be explain in large part by the mineral-rich soil richness favorable to growth from continuous mineralization of sludge even after stopping spreading. In addition, the sludge supply significantly improved the nitrogen content of the seed (Fig.1). This improvement is more pronounced with the addition of urban sludge and could be related to the essential nutrients provided by the sludge.

Effect of sewage sludge on oil content

The oil content of rapeseed is on average 30% (Table 4). As for the sludge effect, we notice that for all treatments of the first campaign no noticeable effect was recorded. While during the second season, we detected a decrease in oil content of 11.42% and 19.65% with the input of industrial sludge respectively at 50t/ha and 100t/ha.

This is essentially relate to the decrease in the weight of the seed. As for the oil yield / ha, it follows the evolution of the production with increases on the sludge plots compared to the soil control.

Effect of sludge on fatty acid composition in rapeseed oil

Rapeseed oil has a very good fatty acid profile, it consists of a minor fraction of 8% saturated fatty acids and about 92% unsaturated fatty acids (fig. 2) including 60% monounsaturated fatty acids mainly oleic acid (c18: 1), which is also found in peanut, olive and sunflower oils and 32% poly unsaturated fatty acids: linoleic acid (c18: 2) and linolenic (c18: 3) [17], [18].

The analysis of the fatty acid composition of total lipids shows an increase in the percentage of oleic acid (c18: 1) at the expense of linoleic (c18: 2) and linolenic (c18: 3) acids under sludge effect (Table 3). This increase in c18: 1 may be a consequence of metal-induced alteration of the process of sequential desaturation of 18-carbon fatty acids. For other acids, such as palmitic, palmitoleic, heptadecanoic, heptadecenoic, stearic, arachidic and gadoleic acids, no effects were recorded. Similarly no difference is recorded with the intake of urban sludge regardless of the dose.

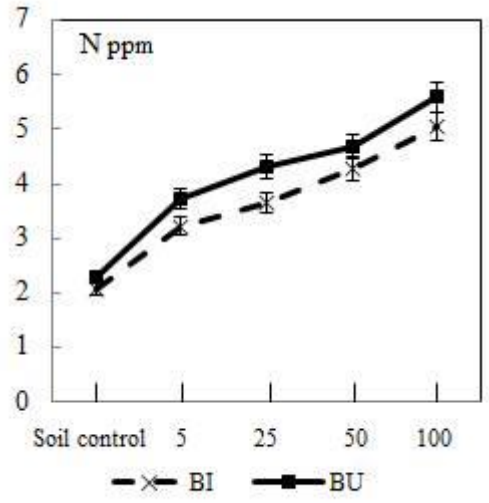

Fig.1: Nitrogen variation content of rapeseeds with increasing sewage sludge doses.

If we compare the composition of total fatty acids for the two companions (table 3), we note during the second application a considerable increase in oleic acid at 50t/ha dose. This acid went from 61.28% (soil control) to 73.33% (50t/ha bi treatment), an increase of 12%. The content of linoleic and linolenic acids in the oil undergoes a greater decrease under the cumulative effect. The highest dose of industrial sludge (100t/ha) resulted in a 52.64% decrease in linoleic acid and 39.39% in linolenic acid. These changes in fatty acid composition do not affect the nutritional quality of the oil. The fatty acid composition of total lipids, shows an increase (fig. 2) in the percentage of mono-unsaturated fatty acids (oleic acid) at the expense of poly-unsaturated fatty acids) in the presence of sludge industrial. The increase of the acid at the expense of linoleic and linolenic acids can be explained by an alteration induced by the metal.

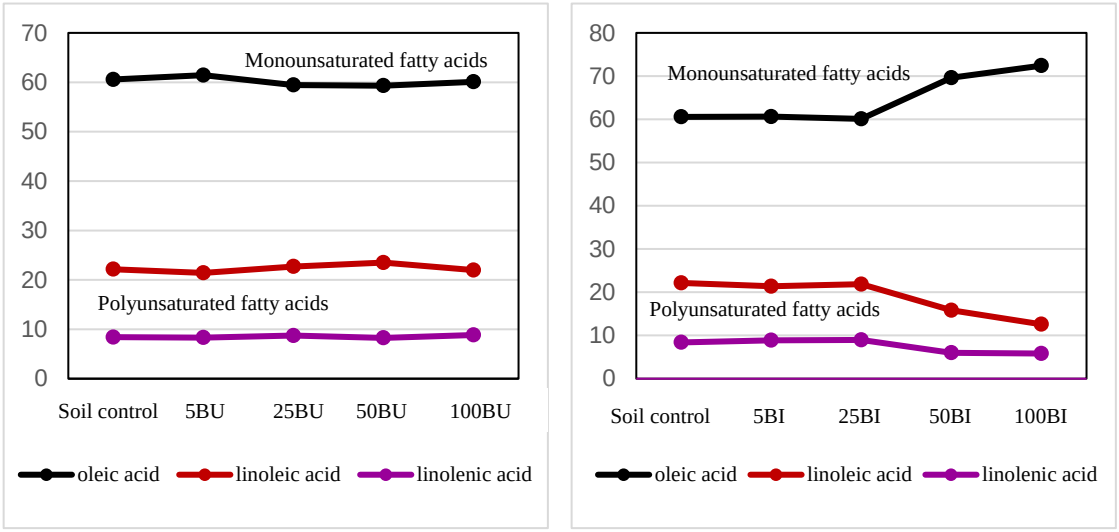

Fig.2 Composition of fatty acids % in Urban and Industrial sewage sludge.

Accumulation of heavy metals in rapeseed

Regarding the action of sludge on the trace metal content of rapeseed, we noticed that the response of the plant differs according to the type of sludge spread, the amount of sludge added and the year of cultivation. The application of industrial sludge essentially modified the Cd and Pb content in the seeds. Thus, we observed an accumulation of Cd with the addition of 100t/ha of sludge during the first year (Fig. 3). This effect was accentuated with the second intake, for which there is an accumulation of 25t/ha (50t/ha cumulative). At the 100t/ha rate (200t/ha cumulative), the contents become 4 times higher. The bioavailability of Cd after cessation of application was also manifested by an accumulation in seeds at 25, 50 and 100t/ha industrial sludge doses. Similarly, we report that, compared to the control, lead levels increase with the addition of 50t/ha of industrial sludge during the first application and the addition of 25t/ha of industrial sludge during the second application.

For the other elements, most grades increase with the addition of sludge. This increase becomes sharper following the second sludge supply for Cr, Ni and Zn contents.

The Cr content (Fig. 4) increase is clearly visible in the presence of industrial sludge where the levels reach with the highest dose of 10 ppm and 15 ppm for the first and second year of application. This accumulation is less pronounced with urban sludge, a maximum of 6 ppm is obtained only with the dose of 100t/ha following the second campaign. The after effect follows the same evolution as for the first spreading in the case of urban sludge. On the other hand for industrial sludge, the rear effect exceeds that of the 1st application but remains lower than the cumulative effect.

Table 4: Evolution of oil content and yield (The values represent the average of four individual repetitions ± (SD)). BU: Urban sewage sludge, BI: Industrial sewage sludge and T: soil control.

	Oil Content (%)		Oil Yield (qx/ha)

25BU	29.88 ±1.8	30.65 ±0.8	3.486	1.704
50BU	29.18 ±1.7	31.08 ±1.3	3.791	1.751
100BU	30.61 ±0.5	31.23 ±1.7	3.739	2.514

The same Cr evolution is observed for Ni for the mud effect, cumulative effect and aftereffect. During the second crop, we also observed Ni increases from 5t/ha, regardless of the type of sludge (Fig. 4). This is quite normal given the quality of the two types of sludge spread including the very high load of industrial sludge in Cd, Cr, Ni and P.

For zinc (Fig. 5), the only difference with the elements previously reviewed is the rear effect which is slightly less important than the first spread for both types of sludge. This could be explained by the high

Zn mobility, which would probably have migrated laterally, or at depth which has blurred the after effect.

The Co contents increase significantly in the seeds (Fig. 6) with the contribution of 5t/ha of urban sludge and remain constant whatever the year of the application whereas for the industrial sludge the Co levels increase significantly from the 25t/ha dose. All effects (direct, cumulative and aftereffect) are very close. The Co contents are higher in the presence of 100t/ha of sludge (Fig. 6).

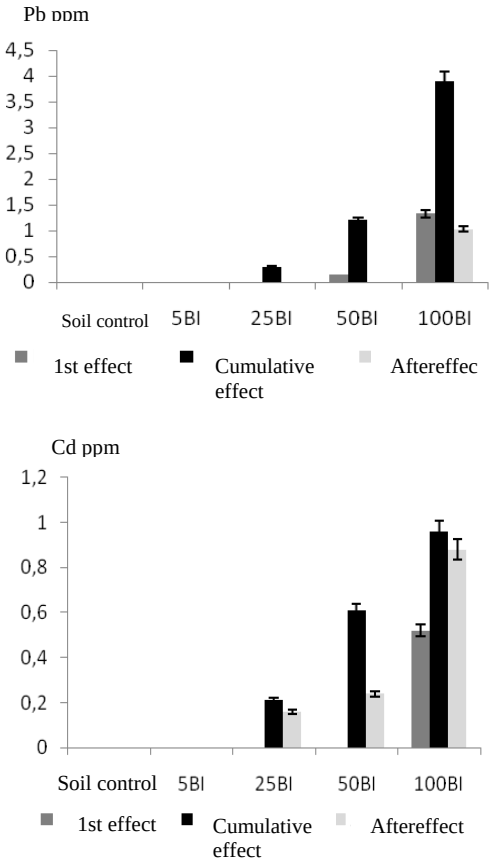

Fig.3: Cd and Pb content variation in rapeseeds grown in the presence of increasing doses of urban and industrial sludge in the first and second year of application.

Evolution of heavy metal contents in rapeseed oil

Analysis of heavy metal data in rapeseed oil (Table 5) shows that all trace metals are present in the oil. Nevertheless, some modifications have been noted.

For urban sludge, no significant difference in heavy metal concentrations was observed with the addition of different doses, even after two years of application. On the other hand, we detected differences with the contribution of industrial sludge loaded with metallic trace elements.

We have observed increases in most heavy metals especially for high doses. The Cd levels increase significantly with the addition of 100t/ha of industrial sludge, from 1.1 ppb (soil control) to 7.3 ppb during the first year and reach 25ppb following cumulative intake. During this 2nd year, the sludge effect was observed at 25t/ha. The Pb and Cr contents increase is mostly visible at 100t/ha. These increases become more important in the second year when the 100t/ha dose levels are 3 to 10 times higher than the soil control. For nickel, grades are higher compared to the control when 50t/ha of industrial sludge is applied to both applications. Regarding Cu, Zn and Cot no effect doses or sludge types were noted.

DISCUSSION

Intensification of human activities, especially industrial and agricultural activities, have contributed in recent decades to the contamination of agroecosystems by heavy metals [19]. The agricultural valorization of the waste sludge can be a source of pollution in the sense that they can contain toxic compounds [20], in particular the metallic trace elements (Pb, Cd, Ni, Cr) whose presence constitutes an obstacle to their use [21]-[23]. This sludge is rich in nutrients and is a significant source of nitrogen, phosphorus and micronutrients that must be used to save fertilizer and provide environmentally beneficial sludge removal [24]-[26].

In this perspective and to contribute to the valorization of sludge, several studies have been carried out. The present work on an open-field rape crop aims to study the effects of different types and doses of sewage sludge on seed yield, seed chemistry and rapeseed oil quality.

During the first and second spreading's, the grain yield increased significantly following the application of urban sewage sludge. The increase in biomass and grain yield has been reported by several authors [27]-[29]. This beneficial effect can be related to a continuous release of nitrogen and phosphorus sludge. We also found that industrial sludge improves production but in a less important way than urban sludge. This may be due to a depressive effect relating to the heavy load of industrial sludge including Cd, Cr, Ni and Pb.

At the same time, industrial sludge caused a decrease in the weight of thousand seeds following the second intake from the 50t / ha dose. This has been accompanied by a decrease in oil production. The metal load of this sludge can be the cause of this disturbance. Ben Youssef et al. [30] showed that the oil content shows a decrease proportional to the metal dose.

The application of industrial sludge also induces increases in metal contents in rapeseeds, while for urban sludge, the modifications are attenuated.

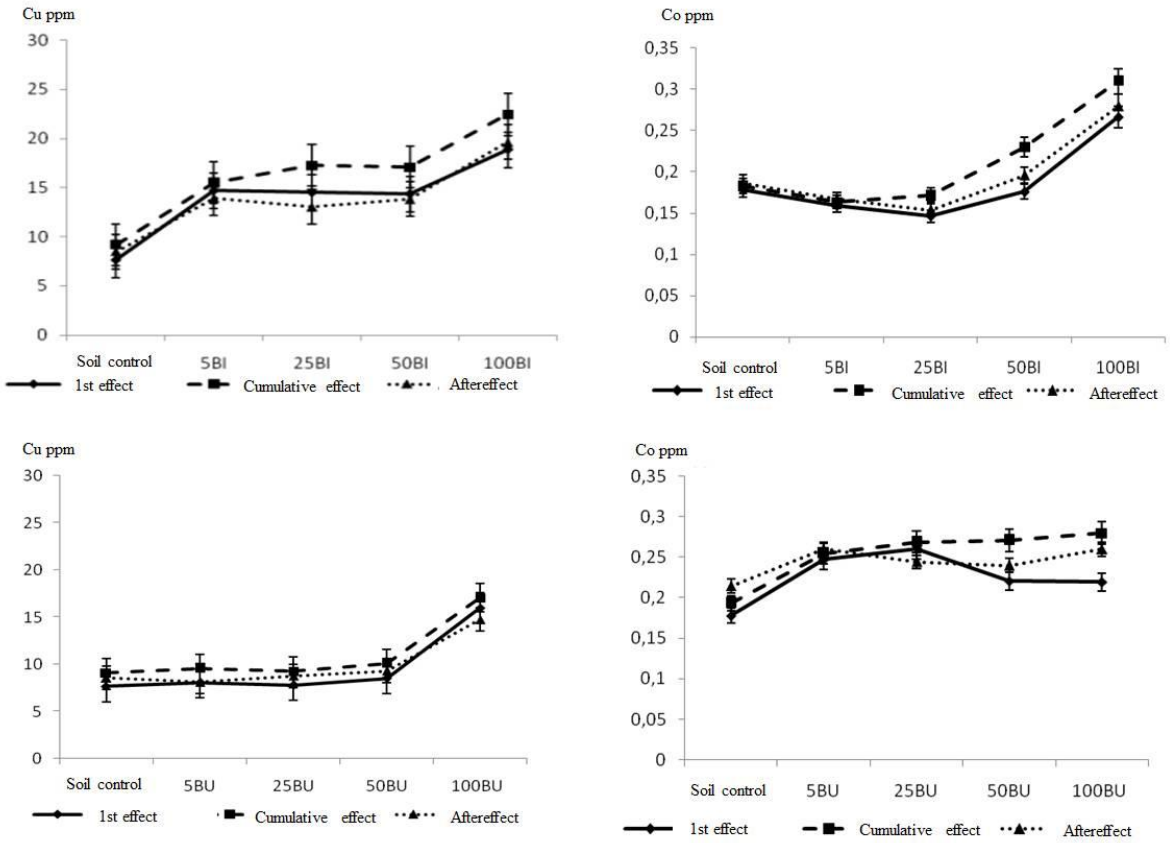

Fig.6: Co and Cu content variation in rapeseeds grown in the presence of increasing doses of urban and industrial sludge in the first and second year of application.

The typical effect of sludge is clear. For both types of sludge, the dose effect is visible. The highest levels are recorded with high doses including 100t/ha. For industrial sludge, the levels obtained at this dose exceed the authorized limits for cadmium, chromium, copper and zinc [31]. Amin and Sherif [32] found the same result where lead, cadmium, nickel and chromium concentrations of bean seed due to sludge application were generally higher than normal values.

The analysis of the fatty acid composition of total lipids shows an increase in the percentage of oleic acid (18: 1) at the expense of linoleic (18: 2) and linolenic (18: 3) acids in the presence of industrial sludge. From a nutritional standpoint, these modifications do not seem to call into question the quality of the oil despite the drop in its yield. According to Darrakech et al. [33] after the refining stage, no risk to human health could be identified with respect to rapeseed oil as it will have decreased levels of heavy metals. On the other hand, increasing the level of 18: 1 acid at the expense of linoleic and linolenic acids can be explained by a metal-induced alteration of the process of sequential desaturation of 18-carbon fatty acids.

MINING REGULATION AND IT'S IMPACT ON PUBLIC WELFARE

Hamartoni Ahadis[1], Wan Abbas Zakaria[2], Irwan Sukri Banuwa[3], Lindrianasari[4]
[1]Ph.D. Student of Environmental Science, University of Lampung, Indonesia;
[2,3,4]University of Lampung, Indonesia.

ABSTRACT

This study aims to provide empirical evidence on the impact of mining company policies in Lampung Province on improving community welfare. The issue used in this study was the enactment of Law No. 23 of 2014 which transferred the authority to manage mineral and coal mining to the Province (previously managed by the Regency/City). This study separates two periods of observation, namely before and after the authority to administer affairs in the mineral and coal mining sector has shifted to the provincial government. Using secondary data derived from records of receipts sourced from mining companies in each region for five years of observation (2010-2014 for the before period). While the 2015-2018 data will be collected from the government of Lampung Province, because since 2015 the authority to administer affairs in the mineral and coal mining sector has shifted to the Provincial government (2015-2018 for the after period). This welfare is measured using local original income. The greater the annual average local original income from mining received by the Province compared to the average accumulated annual local original income from mining received in all districts / cities in Lampung, the welfare index in Lampung Province also increases. The results of the 2010-2018 analysis show an increase in local original income from mining companies after the enactment of Law No. 23 of 2014. This finding indicates that mining regulations issued by the government improve community welfare and confirm regulatory theory, especially the theory of public interest.

Keywords: Regulation, Mining Companies, Public Welfare.

INTRODUCTION

Mining companies are companies that are very sensitive to the environment, because their operational activities are exploiting natural resources. Because the impact of environmental damage caused by the activities of this company is quite large, the policy on social responsibility and the environment of mining companies must be designed by the government. Without policy, ecosystems in the region will be threatened, and conflicts between communities and companies will increase. In this condition, government interference must be able to deal with problems that might arise from mining activities. From the company side, the social and environmental responsibility of mining companies should not be limited to Philanthropy but must be within the company's business strategy [1]. Thus, social and environmental accountability will indeed be managed by considering the relevance of the program to the activities of the company.

Through Law 23 of 2014 concerning Regional Government, mandates the authority of the Provincial Government in the field of energy and mineral resources. This law is strengthened by the Minister of Energy and Mineral Resources Circular Letter Number 04.E / 30.DJB / 2015 which confirms that the Regents / Mayors no longer have authority in the administration of minerals and coal.

This condition may be driven by the note that funds that must be deposited from mining companies to regional governments are still very low. Government revenues from mining activities are defined contributions, such as; exploration fees (work contracts/ feasibility studies, construction), exploitation contributions (Royalties) and other payments related to the granting of mining rights (Decree of the Minister of Finance of the Republic of Indonesia number 344 / kmk.06 / 2001).

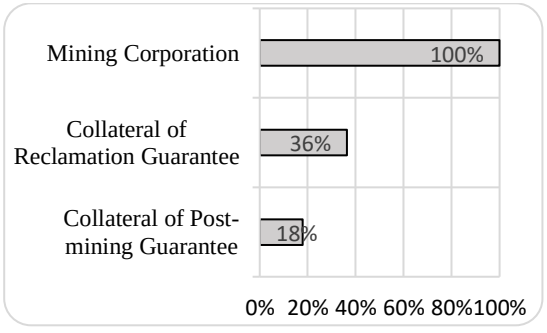

Fig. 1 Collateral for reclamation and post-mining guarantee in Lampung Province, 2018.

The low awareness of mining companies to provide guarantees of reclamation and post-mining, is shown in Figure 1. From figure 1, it can be seen that there were only 36% of mining companies out of a

total of 168 companies that paid collateral for reclamation. Meanwhile, companies that pay post-mining guarantees are only 18%, and all of them come from companies that also pay collateral for reclamation.

LITERATURE REVIEW

Regulatory theory, specifically public interest theory, introduced 1934 in the book The Economics of Welfare [2], explains that the policies issued by regulators are in the interests of the people, namely improving inefficiency and injustice in practices that occur in the field. Lindrianasari et al. [3] found that the theory of regulation (particularly for public interest theory) can explain clearly the reasons why the four variables research has increased after the environmental regulations issued. Their research found similar results in all companies listed on stock exchanges in three developing countries, namely Indonesia, Malaysia and Thailand, related to new policies on social and environmental responsibility.

Deegan and Unerman [4] explained that policies will not only bring benefits to the people but also to protect the environment and maintain sustainability. Regulatory theory predicts that policies issued by the government related to the authority of environmental management (in terms of activities of exploitation of natural resources), should be able to improve the quality and sustainability of the environment.

The stakeholder theory explains which parties the company must be responsible for [5]. At the very least, the company must be able to maintain its relationship with stakeholders, by fulfilling obligations that are the will and needs of stakeholders, including powerless-stakeholders. In this case, the company must ensure the availability of resources used for the operational activities of the company and the surrounding community.

In line with Law 23 of 2014 concerning Regional Government which mandates the authority of the Provincial Government in the field of energy and mineral resources, the assessment of social impacts on mining is an important matter. The purpose of this social impact assessment is to see whether regulatory theory can be confirmed in the application of the law. At present, there is no global regulatory system or an international legal system can force companies to be responsible for their operations in weak governance zones [6]. Because in weak governance zones, social and environmental problems are relatively higher, vice versa. Therefore, there must be an alternative accountability mechanism that applies at least within the scope of the state and the region that regulates corporate social responsibility. Enforcement of the Act 23 of 2014 has become the answer to the needs of regulation in mining issues in Indonesia.

As the company aims, mining activities are managed to generate profits. But if there is mismanagement, mining activities can have a negative impact on human society, the environment, even for the sustainability of the company. The study conducted a test of how people around mining companies evaluate the benefits and negative impacts of mining has been carried out in Australia. Evaluation is carried out on communities around mining about the influence of the order of life of communities around mining [7]. They found that strong governance will increase the respect of the community towards the company relatively higher compared to when governance is weak, even when environmental conditions get worse.

Mining companies, are one of the companies that can be the highest source of state income. Even in the Democratic Republic of Congo (DRC) mining companies are expected to contribute 50% of GDP in 2015 (Reuters, 25 October 2010) up from 23-25% in 2010 [8].

From theoretical, practical explanations, and supported by previous studies, the research hypothesis is formulated as follows:

Ha: Government policies on management authority in the field of energy and mineral resources improve public welfare.

RESEARCH METHOD

This research is a preliminary study conducted on the impact of the issuance of Law 23 of 2014 concerning Regional Government, regarding the transfer of management authority in the field of energy and mineral resources from the Regency / City Government to the Provincial Government. This law has also been strengthened by the issuance of the Minister of Energy and Mineral Resources Circular Letter Number 04.E / 30.DJB / 2015.

The research method used in this study is to involve the mining office in all cities and districts in Lampung Province. By using secondary data from two different recording sources. First, sourced from the mining offices of each district / city for data on revenues from mining companies in each region for the five-year period (2010-2014). Second, sourced from the environmental office for data acquisition from 2015-2018. The mechanism for obtaining data is by collecting it centrally at the Lampung Province government office. Moreover, since 2015 the authority to carry out affairs in mineral and coal mining has shifted to the provincial government.

This study will investigate the benefits of central government policies through Law 23 of 2014 concerning Regional Government. Whether after the authority in administering government affairs in the field of mineral and coal mining is transferred to the Province, public welfare will be better. This welfare will be measured by using Regional Original Income (PAD). The greater the annual average PAD from

mining received by the Province compared to the average accumulated annual PAD from mining received in all districts / cities in Lampung, the welfare index in Lampung Province also increases.

RESULT

This research will determine the different test of regional original income from mining obtained in Lampung Province. Before and after the enactment of Law Number 23 Year 2014, which transferred the authority to manage mineral and coal mining to the Province (previously managed by Regency /City). This regulation of substance is not only transferring management, but furthermore, this movement aims to provide greater authority to the Province to apply the pattern of uniformity that is applied to the mining sector to be responsible for the exploration and exploitation activities they carry out. With this pattern of uniformity, it is expected that the transparency and accountability of fund management from the mining sector will be better, and the misuse of funds can be minimized.

Regional Original Income when authority for the management of mineral and coal mining in Regency/City

Regional original income obtained from the mining sector four years before the transfer of authority for the management of mineral and coal mining to the Province, in accumulated from 15 Regency/City in Lampung Province, is shown in figure 2 and figure 3. Figure 2 shows local revenue originating from contributions fixed and royalty, while Figure 3 shows the total regional income from the mining sector.

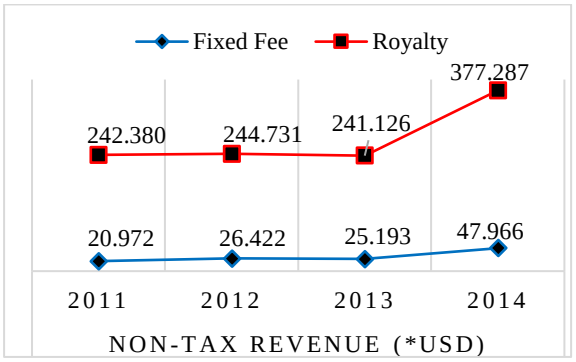

Fig. 2 Non-tax Revenue from fixed fee and royalties (Before).

Figure 2 shows that income from fixed royalty fees before 2014 tends to be low (stable). But this was not the case in 2014, when the government issued its new policy. Even though Law number 23 of 2014 was effectively implemented in 2015, the fixed fees and royalties obtained from the mining sector showed an increase. So that we can visually see how the new regulation affects regional revenues. In Figure 3, it shows how the total revenue from the mining sector increased in 2014, in line with the income from each fixed contribution and royalty increase in 2014. These findings indicate that regulations will form a legal certainty of how a person or entity behaves, in line with the rules made.

Fig. 3 Total Non-tax Revenue from fixed fee and royalties (Before).

Regional Original Income when authority for the management of mineral and coal mining in Province

Data from the Lampung Provincial Government shows an increase in the total non-tax revenue from the mining sector over the past 4 years (2015-2018). These results indicate an increase in the welfare of the community, assuming the rate of return to the community is directly proportional to the total non-tax income.

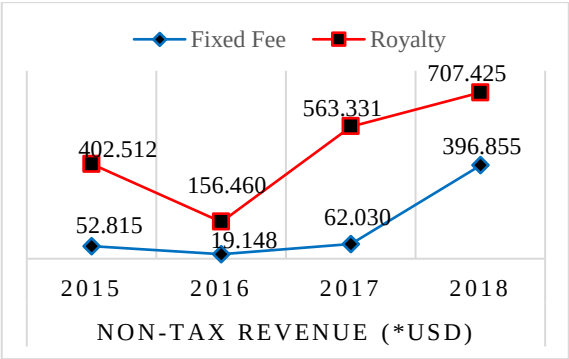

Fig. 4 Non-tax Revenue from fixed fee and royalties (After).

Since the enactment of Law 23 of 2014 which transferred the authority to manage mineral and coal mining to the Province (previously managed by the Regency/City), there has been an increase from sources of income from mining to the government. Figure 4 shows the growth of non-tax revenues originating from fixed fee and royalties of mining companies. Meanwhile, figure 3 shows the total non-tax revenue obtained by the province. Both images

show non-tax revenues from mining over the past 4 years after the management of mineral and coal mining management was transferred to the province, which was previously managed in the district /city.

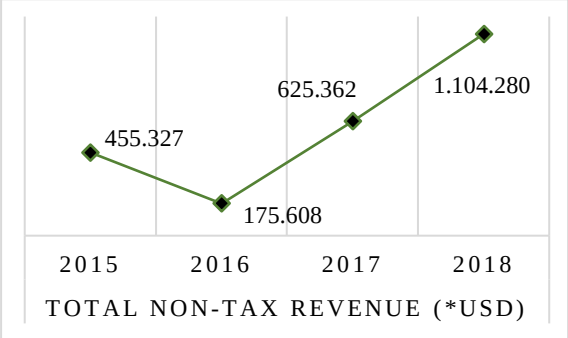

Fig. 5 Total Non-tax Revenue from fixed fee and royalties (After).

Figure 4 and Figure 5 show the growth of non-tax revenues obtained from mining companies. The income of the provincial government from the mining sector has been able to increase the amount of local revenue. Therefore, it is assumed that the higher the local revenue, the better welfare of the people in Lampung province.

The main operation of a mining company is to explore and exploit natural resources. Meanwhile, around the area where the company is exploring and exploiting, there are other interests that require a balanced ecosystem for a good life. For this reason, the function of the government is required to cover all the interests of the parties in this area, so that no party can obtain maximum benefits, while other parties only get negative impacts from mining activities.

The government must show its role as regional leader. The role of the government must be to minimize gaps between community groups and groups of companies, and / or in one region with other regions. Therefore, the existence of regulations that take over the authority at the lower level to a higher level is highly expected to create better welfare equality. Law 23 of 2014 concerning Regional Government which mandates the authority of the Provincial Government in the field of energy and mineral resources is one of the regulations that is expected to create welfare equality. This law is also strengthened by the Minister of Energy and Mineral Resources Circular Letter Number 04.E / 30.DJB / 2015 which confirms that the Regent / Mayor no longer has the authority to administer government affairs in mineral and coal mining.

Test the Comparison of Original Regional Income Before and After the Enactment of Law 23, 2014

We conducted an independent sample t-test to assess differences in government revenues from the mining sector before and after the enactment of Law 23 of 2014. The reason for using this test is because we use the average income for 4 years before and 4 years after, so the total sample used is < 30.

Table 1 Comparison test

Levene's Test for Equality of Variances	
F	10.100
Sig	.034
Equal variances not assumed	
t	-4.177
Sig. (2-tailed)	.047*

Note: *significant at the 0.05 level.

The results of the homogeneity test using the Levene's test method show the value based on Mean, which is 0.001 with p value (sig) of 0.034 where > 0.05. These results indicate that there are inequalities in variance between groups or heterogeneous. Therefore, we use the value of equal variances not assumed to determine whether there are any differences between the groups tested. Table 1 shows the results of the independent sample t-test.

The result of equal variances not assumed shows the t -4,177 with sig. (2-tailed) 0.047 <0.05 which indicates that the regional original income from the mining sector after the application of Law 23 of 2014 was significantly higher. These results mean that what is predicted by regulatory theory (public interest theory) that policy should be publicly confirmed is confirmed through this research. Because with the increase in the amount of local revenue, the greater funding can also be made in the area to improve the welfare of the community.

This finding is in line with previous research which found that the intervention of developing country governments greatly determines the company's compliance in considering social and environmental aspects [8]. This finding also indicates that the government issued a new policy to regulate the management of funding revenues from mining activities to improve community welfare. This finding concludes that the hypothesis of this study which states that government policies on management authority in the field of energy and minerals improve public welfare, is supported.

CONCLUSIONS AND SUGGESTIONS

This study found a significant increase in regional original income in Lampung Province after the enactment of Law No. 23 of 2014. This finding also shows that the aim of the government in issuing a new policy is to manage the amount of funds in the regions from mining activities which has succeeded in increasing the revenue of the Province.

Although this study was only conducted in Lampung Province, this study can be used as a reference that the regulations issued turned out to be in favor of the interests of the community. Because with the increase in local revenue, capital expenditure for the community is also expected to increase. That way, people's welfare will increase with this new policy.

This study can be applied to other regions in Indonesia. Future research can use the same approach and / or use other approaches, to test the superiority of the issuance of laws relating to the management of mining (related to the environment and social community). Further studies are also expected to expand research content, by combining secondary and primary data (surveys into the community) so that subsequent studies can provide more comprehensive and useful results.

The limitation of this study is that it is difficult to collect data from each district / city mining office because, since 2015, this section has been abolished and merged with the environmental office. This transition might cause the existence of documents to be incomplete.

ACKNOWLEDGMENTS

This paper can be completed thanks to the support of many parties. A valuable discussion with my colleague is the Doctor of Environmental Sciences program, University of Lampung, fellow practitioners from a mining company in Indonesia, head of the mining service, head of the environmental office, in Lampung province. All discussions and data help have made this paper more qualified. For all support, we are happy to thank you.

FOUNDATION, SUPPORT AND DEVELOPMENT OF THE REPUTATION IN COMPANY

Svetlana D. Gurieva[1]

[1]Professor, Department of Social Psychology,
Saint Petersburg State University, Saint Petersburg, Russia

ABSTRACT

This research work covers issues related with the main principals of foundation, support and development the reputation. We have collected a variety of definitions of the concept of “reputation" that are presented in different spheres: economics, marketing, sociology, organization theory, and received the modern understanding the reputation phenomena. Considering the structure of reputation, the main role in the formation and maintenance of reputation plays the owners, managing staff, employees, clients. The study involved 350 people from the Company, of which 14.2% were men and 85.8%, were women from 18 to 67 years old. The objective of our research is to study the socio-psychological representations of reputation in the context of the organizational culture. The study used the following tools: Questionnaire, Sacks sentence completion test by Sacks and Levy. A meaningful and statistical analysis of the results based on the method "Unfinished sentences" allows us to formulate several statements. We found practical confirmation that the foundation of reputation is perceived as honesty, credibility, openness, reliability, quality of products and services that is the core of company′ reputation. Theoretical analysis of strategies for the formation, maintenance and development of reputation shown that its can be a platform for the development of intra-organizational strategies aimed at maintaining the high reputation of the company. The development of the reputation is based on visibility, transparency, coordination and emotional appeal. All the above is a confirmation of the existence of a strong internal corporate reputation management that studies the specifics of building reputation.

Keywords: reputation, social representation of reputation.

INTRODUCTION

Fombrun C., Shanley M.S. (1990) suggests that reputation itself should be understood as a social assessment of someone's specific characteristics, “the reputation is an active assessment of respect for a man by himself and showing the respect for people’s opinion about him" [8]. According to S. Gorin (2006), who considers a business reputation as the economic-legal category that is the “general prevailing opinion about the qualities, merits and demerits of the organization in the field of business turnover, which determines the attitude of the environment and can generate above-standard profits" [11, P. 25-26]. R.J. Varey [19] focuses on the use of the term “reputation" in the business environment and provides these definitions and statements about the concept of corporate reputation: the combined experience of all people who interact with the organization (Friedman, 2009) [9, P. 229-244]. The assessment of respect for the organization that reflects the image created by people (Dowling, 2001) [5]; the reputation of a company is partly the function of its own activity (including PR-actions) and partly of the behavior of those groups of people who show interest in it or are directly related to (Griffin, 2009) [12]. V. Safón gives the following definition of the reputation as “perceptual presentation of the past actions of the company and its future plans which describe the overall attractiveness of the company according to its key components compared to the competitors” [18, P. 205]. Thus, as it is seen from the definitions of reputation, most authors agree that the reputation is certain information concerning the qualitative aspect of human activity or company [1], [3], [12], [10]. We have collected a variety of definitions of the concept of “reputation" presented in Fig.1.

In the specialized literature, the most commonly used concept of reputation is used in conjunction with the concept of corporate image. The set of beliefs and feelings associated with a particular image that enriches it with meaning or psychological content. This is the interaction of a company’s presentations of itself, the way it would like view and the real public opinion about it, whose changes are difficult to understand [19]. From our point of view, the essence of the reputation and image have a number of common points, but they are not the same [2]. Thus, an image is a specific symbol, a position being deliberately created and promoted by a person or an organization in public. A reputation is the way the image of a company is perceived and how it is viewed in the public eye. The authors argue that reputation is a broader concept and includes the image [13], [16], [13], [15].

Having considered the model of confidence and the structure of relationships in the organization let us pay attention to the specifics of the confidence in the organization (Fig. 2).

Discipline	Definition
Economics	Reputations are traits or signals that describe a company's probable behavior in a particular situation.
Strategy	Reputations are intangible assets that are difficult for rivals to imitate, acquire or substitute.
Marketing	Reputation describes the corporate associations that individuals establish with the company name.
Communications	Reputations are corporate trails that develop from relationships companies establish with their multiple constituents.
Organization theory	Reputations are cognitive representations of companies that develop as stakeholders make sense of corporate activities.
Sociology	Reputational ranking are social constructions emanating from the relationships firms establish with stakeholders in their shared institutional environment.

Fig. 1. The definition of corporate reputation.

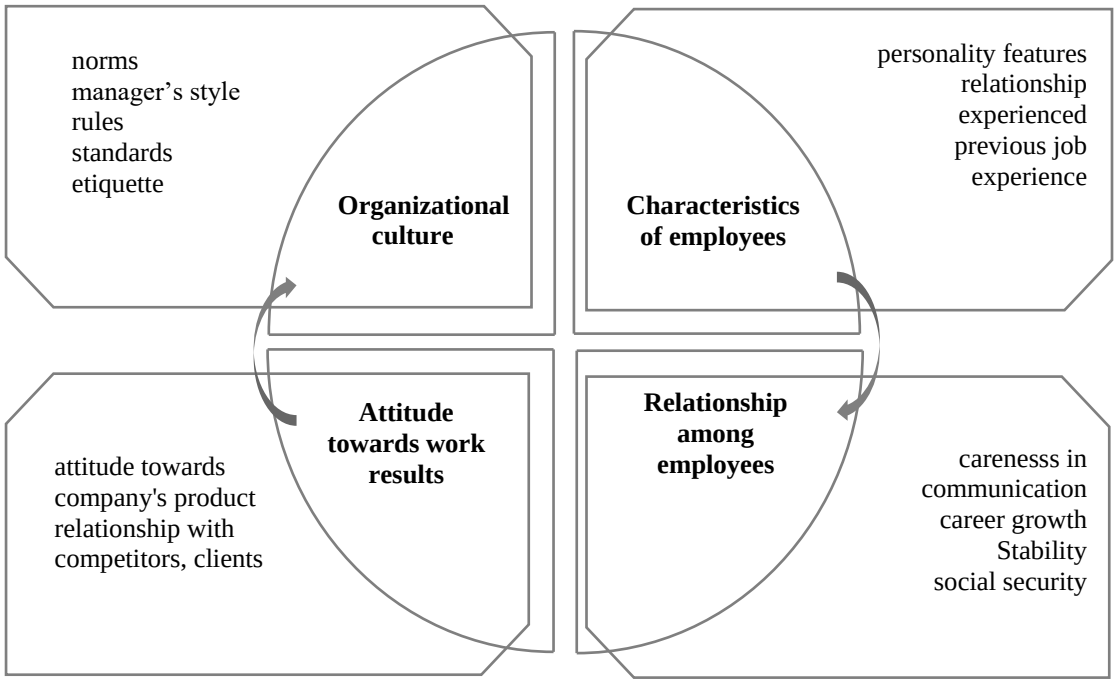

Figure 2. The model of confidence forming in the organization (Gurieva S., and others, 2016).

According to M. Armstrong (2006), the basis for forming the reputation, organizational confidence and image is the organizational culture being shaped under the control of company's management representing, a set of beliefs, attitudes, norms of behavior and values that are common to all the employees of the organization. Not always they can be clearly expressed, but in the absence of direct instructions they determine the ways people act and interact and they greatly affect the progress of the work. By forming the organizational culture, managers have the ability to control and modulate the optimal level of the staff. Also, the employees themselves may affect the common standards by their attitude towards them, duty and aim to meet them. Each of them does not only possess his own personal features that determine the ability to confidentially interact, but also the experience of previous professional relationships. This should be taken into consideration at the stage of adaptation of an employee, thus attitudes formed towards the image of the leaders, colleagues and subordinates have a direct impact on building relationships within the new team.

There are two factors affecting both level of trust in the organization and company's reputation. First of all, what does mean is the level of common well-being, satisfaction of such needs as the need for stability, security, career opportunities. Second, it is made up of confidence in the product, in the result of the organization, in the value of the staff themselves. These are the consumers and customers for goods and

services who affect the attitude towards the product, as well as competitors forming a picture of the position of the organization in the market.

The company's reputation is built on the values, which are the features of a particular company (authenticity, integrity, responsibility to customers, etc.). However, at some point, the author begins to use the concepts of image and reputation, separated by commas, without making distinctions between them [5]. Reputation is a better-considered, reasonable perception of the object, based on the achieved experience, containing the assessment. The image is the upper stage of knowledge and is a correlation of the communication process with the personal human experience, through which stereotypes and certain models of behavior are created [2]. Thus, it can be concluded that the reputation is more complicated concept compared to the other two. It includes brand (emotional) and substantive (based on personal experience) parts, the latter of which is based on the image [8].

Reputational nature of organizational culture in its turn, has an impact on the marketing symbol (brand assets), strengthening the positive association with the company, the perception of quality, increasing commitment and loyalty (Dowling, 2001; Martin, G., Hetrick S., 2006). It is necessary to demonstrate ethical values, the importance of employees and customers [15]. However, in different social groups, the strategies for building reputation differ and corporate identity and corporate image in people's minds are not always identical [5]. One may say that for building business reputation it is necessary to communicate with different target audiences, focus on their opinions and preferences, as the decision about quality of the reputation is being made on the auditor's assessment. It is subject to be assessed by the state, the competitors, the partners, the investors, the customers, the staff and the local community (Dowling, G. R., 2001; Martin G., Hetrick S., 2006; Griffin A., 2009; Fombrun C., Shanley M., 1990; Fombrun C., Van Riel C., 2004; Friedman B. A., 2009). G. Dowling (2001) divided all these types of social groups into 4 ones:

1. Regulations (establishing general laws and rules of doing business: authorities, government and non-government organizations, international credit rating agencies);
2. Functional (influencing the daily life of the organization: staff, suppliers, distributors, consulting and juridical firms);
3. Diffuse (indirectly related to the organization, but influencing its reputation, there can be potential customers i.e. journalists, environmental organizations, etc.);
4. Consumers [5].

Making the reputational strategy involves the goal setting, development of certain activities in order to form it and understanding the features of target social group. Mailath G., Samuelson L., (2001) view a reputation as an asset, and building a reputation requires three following principles:

- *Reputation is built gradually*. The consumer trust that lies at the basis of a reputation is accumulated in response to sustained, high-quality work.
- *Reputation disappears gradually*. A firm that stops investing in its capital stock and lowers the quality of service does not experience an immediate decline in reputation till a consumer adjust to the new level of working standard.
- *Reputation can be managed*. The quantity of investment can be regulated. Thus, the initial periods of development demand higher investment level than later periods when the company is mature and its reputation is sustained without essential investment.

This and much more will make the company be more attractive for both employees and customers, and increase its value. In order to create reputational strategy due to modern conditions it is necessary to take into consideration the following features of the world affecting the quality of companies' reputation:

1. *Widening boundaries of the world* (widening the boundaries of movement and increasing information streams make a man's life more public and available for society);
2. *Increasing dangerous cases* (the will to feel safe and secure under the current circumstances of increasing life intensity causes the keen attention to the risks);
3. *Informational saturation of the world* (the increased speed of reaction to new event, information acquisition and production);
4. *Society obtained true power* (attention to the needs of its target audience i.e. the consumers, the employees, the state etc.);
5. *Increasing influence of non-governmental organizations on the society and economics;*

«State remains strong but business weakens» (the demands and critical to the companies and their reputations increase) [12].

Reputation is one of the factors in building trust in a company. Many researchers have studied relationship between trust and reputation, as well as the mechanism of their formation in the conditions of market economy. The relational approach is commonly used, according to which the company's reputation and credibility of the system are considered as complementary components (Fig. 3).

That is the example of creating trust according to G. Dowling (2001). In this regard, to build the reputation companies should be able to differ from others, to carry out the obvious and consistent strategic actions, express their beliefs and values openly. It is necessary to show sincerity, interest in their target groups, thereby causing confidence.

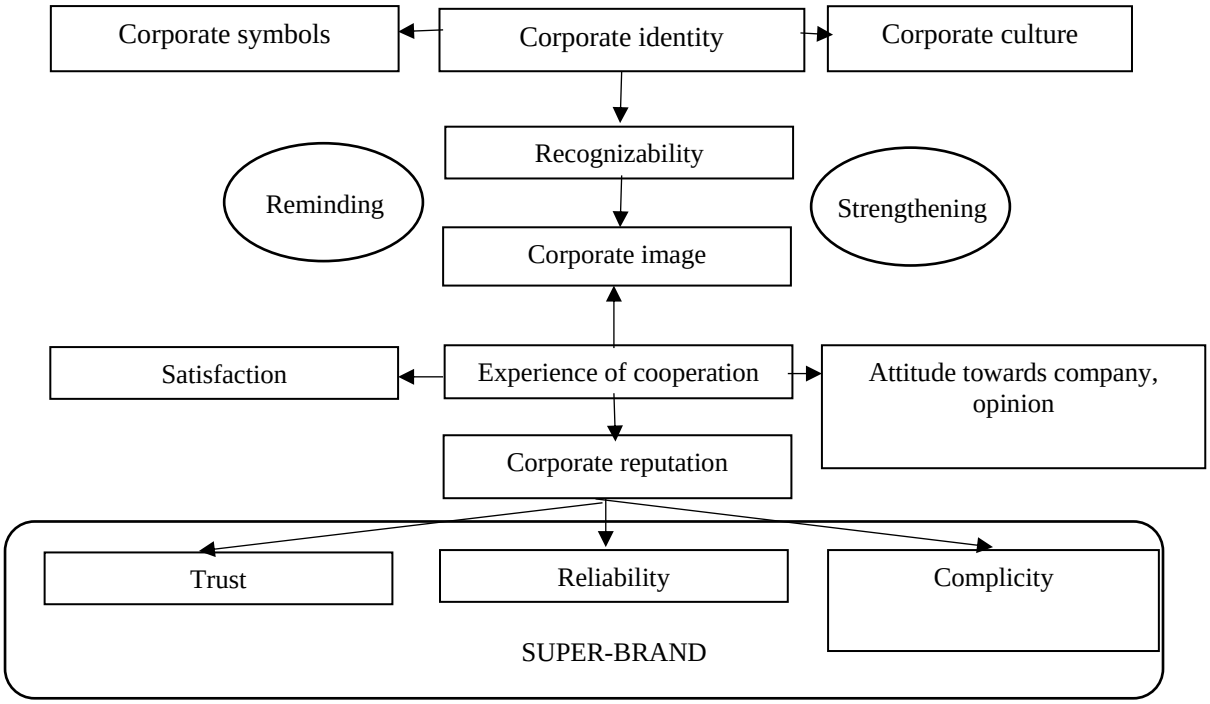

Fig.3. Reputation components (based on: Fombrun, Van Riel, 2004; Gurieva, Manichev, 2016).

THE IMPORTANCE OF ORGANIZATIONAL CULTURE FOR BUILDING A STABLE POSITIVE REPUTATION.

The transformation of a favorable image of an organization to the intangible asset ***starts from inside***, it must be transparent and integrated not only in the strategic management of the company (affecting goals, vision and mission of the company), but also embedded in the ***organizational values.*** Features of the organizational culture, reflected in both the actions of employees and the organization as the whole, play a major role in determining the nature of the company's business reputation in public, media and the state, as well as the specifics of corporate reputation, which is important for shareholders, creditors and investors. In other words, the concern for creating a stable reputation should be reflected in the organizational culture of the company, and corporate reputation should be perceived as a part of it. Many theorists and practitioners studying the reputation of companies agree with that thesis including A. Griffin (2009), S. Greyser (2009), B. Friedman (2009), O. Harpur (2001), V. Safon (2009) and others.

Proper human resource management as an element of organizational culture obtains particular importance to create a strong reputation. "Styles of behavior affecting the reputation and brands depend on the level of education, skills and abilities of the total human capital bank" (Martin G., Hetrick S., 2006, p. 36). In order to increase the loyalty of employees, according to Fraser P. Seitel (2014), one must keep the following principles: respect, frank feedback, moral encouragement, right to vote. However, this might not be sufficient. According to Griffin A. (2009), the company's reputation is appreciated by employees only when caring about it is embedded in the system of bonuses. In this situation, the special role in building the organizational reputational culture is given to the Department of HR, which increases the motivation of employees and their identification as a part of the organization through the following roles (Friedman, 2009).

No less significant is the *figure of the manager* who seems to reflect the company's values and transmits them first of all to the internal organizational environment, defining the character of the organizational culture. The manager carries the weight establishing delicate balance among organizational identity, corporate image and brand necessary for building the reputation. If the direction chosen by the selected leaders is not approved by employees, then there is a gap between the leader and his vision of culture. If values stated by the brand are not implemented that shows the divergence of image and corporate culture, which leads to confusion of customers and employees. In the case in practice when image and vision diverge, managers' aspirations do not coincide with the external image of the company (Martin G., Hetrick S., 2006).

The manager is the first person of the company both for employees and for all external audiences, to a greater or lesser extent related to the activities of the company. The image and reputation of the head definitely affect the nature of the company's reputation, but to use the head as a symbol of the company's

reputation would be the risk [5]. In this regard, the leader must not be only famous, but also authoritative, which is not synonymous. Accordingly, a successful manager who wants to create a favorable image of his company, should have the following features:

- a clear definition of objectives;
- the ability to inspire confidence;
- the ability to exercise effective crisis management;
- mergers and acquisitions management;
- formation of the company's reputation in the media;
- the influence on stock prices changes [5].

REPUTATIONAL NATURE OF ORGANIZATIONAL CULTURE.

Reputational nature of organizational culture in its turn, has an impact on the marketing symbol (brand assets), strengthening the positive association with the company, the perception of quality, increasing commitment and loyalty (Dowling, 2001; Martin, G., Hetrick S., 2006). It is necessary to demonstrate ethical values, the importance of employees and customers. However, in different social groups, the strategies for building reputation differ and corporate identity and corporate image in people's minds are not always identical (Dowling, 2001). One may say that for building business reputation it is necessary to communicate with different target audiences, focus on their opinions and preferences, as the decision about quality of the reputation is being made on the auditor's assessment. It is subject to be assessed by the state, the competitors, the partners, the investors, the customers, the staff and the local community (Dowling, G. R., 2001; Martin G., Hetrick S., 2006; Griffin A., 2009; Fombrun C., Shanley M., 1990; Fombrun C., Van Riel C., 2004; Friedman B. A., 2009). G. Dowling (2001) divided all these types of social groups into 4 ones:

1. *Regulations* (establishing general laws and rules of doing business: authorities, government and non-government organizations, international credit rating agencies);
2. *Functional* (influencing the daily life of the organization: staff, suppliers, distributors, consulting and juridical firms);
3. *Diffuse* (indirectly related to the organization, but influencing its reputation, there can be potential customers i.e. journalists, environmental organizations, etc.);
4. *Consumers*.

Thus, it is important to emphasize that the broadcasting reputation in a wide range of social

groups that are interested in cooperation with the organization, starts with the values of the atmosphere and culture, rooted in the company. Therefore, the type of organizational focus is crucial in determining the company's reputation.

APPROACH

The main goal of our project is studying the phenomenon of reputation. The study involved 350 people, 14.2% were men and 85.8%, were women from 18 to 67 years old. The participants of the study were asked to complete the 7 sentences which were grouped into 5 major scales and processed using content analysis. 1.Reputation is …? 2. Our company is …3. Reputation is based on the principles of …? 4.I trust the company because … and etc. While studying the phenomenon of reputation, priority is, first, the understanding and further investigation of implicit representations about the notion of "reputation". How to understand the reputation, what they put into the content, what related concepts are mentioned, why they are important. For the frequency analysis of words in tasks with an open response, the stamping procedure was used hat is bringing the words to a unique form. To stemmize the answers, the MyStem program (Yandex LLC) was used. The program MyStem makes a morphological analysis of the text in Russian. A special feature of this program is the possibility of constructing the presupposing parsing for words that are not in the main dictionary, and full support for the Russian language. The text was processed by means of a package for the study of the natural language tm (Feinerer I., Hornik K., Meyer D., 2008) for the statistical medium R (R Core Team, 2017). To provide the results, words that occur at least 5 times were selected.

RESULTS

To test the hypotheses put forward in the study the following mathematical-statistical methods of statistical data processing were used: Content analysis; Comparison of the mean values and standard deviations (Mann-Whitney U-test). For the frequency analysis of words in tasks with an open response, the stamping procedure was used hat is bringing the words to a unique form. Semantic analysis the results of meaning the reputation. Employees of the company consider that the reputation is: the company itself, society, opinion and people; The most frequently repeated terms in the description are the following statements: it is opinion about a stable company, a reliable partner (Fig. 4).

Staff.Reputation.word	Staff.Reputation.freq	percent
Opinon	56	10.7
Company	46	8.8
Society	25	4.8

Fig. 4. Representation of reputation among the interviewed employees.

During its existence on the market, company has proved that it can be perceived as a reliable, partner company, as a reliable and good company, as a stable

and reliable partner company. The main reasons why the interviewed respondents consider company to be reliable and stable is following the basic principles and values of the company. Among them, for example, the consultants note the honesty, quality of products; the leaders and the staff mention the spirit, togetherness and passion (Fig. 5).

Staff. principle. word	Staff. principle. freq	percent
spirit	108	16.2
togetherness	107	16.0
passion	104	15.6
people	17	2.5

Fig. 5. Basic principles of the company among the interviewed staff.

In our opinion, an important achievement and a high level of loyalty and commitment to the company are the responses to the statement "I feel myself the part of the company ...". The overwhelming majority of respondents perceive the company as their own, as part of themselves, as the greatest value in their lives (Fig. 6).

Staff. part. word	Staff. part. freq	Percent
company	27	8.9
my	14	4.6
be a part	11	3.6

Fig. 6. Staff about their attitude to the company.

A meaningful and statistical analysis of the results based on the method "Unfinished sentences" allows us to formulate several statements. Our company has stable, positive implicit ideas about the company itself, as well as the company's reputation, from the point of view of the employees. We found practical confirmation that the reputation of the company is perceived as honesty, credibility, openness, reliability, quality of products and services.

Conclusion

The results of our research were reflected with the main principles of forming the reputation and raising the emotional predisposition towards the company described by Charles Fombrun and Cees Van Riel (Fombrun C., Van Riel, S., 2004). Theoretical analysis of strategies for the formation, maintenance and development of reputation can be a platform for the development of intra-organizational strategies aimed at maintaining the high reputation of the company and its further development. The foundation of reputation is perceived as honesty, credibility, openness, reliability. Theoretical analysis of strategies for the formation, maintenance and development of reputation shown that its can be a platform for the development of intra-organizational strategies aimed at maintaining the high reputation of the company. The development of the reputation is based on visibility, transparency, coordination and emotional appeal. The company management should pay attention to the revealed differences in the assessment of the main components of the reputation between the staff, on the one hand, the leaders and consultants, on the other. It is possible to propose for the HR staff the development of special mixed training programs, which will involve representatives of three groups: leaders, consultants and company staff. In the program, include a meaningful analysis of cases, the reflection of experience, and the exchange of experience.

ECOTOURISM DEMAND FORECASTING AT NATIONAL PARK, KUALA TAHAN, PAHANG

Noratikah Abu[1], Megat Muhammad Afif[2], Wan Nur Syahidah[3]and Zuhaimy Ismail[4]
[1,2,,3]Faculty of Industrial Science & Technology, Universiti Malaysia Pahang, Malaysia; [4] Faculty of Science, Universiti Teknologi Malaysia, Malaysia

ABSTRACT

Tourism forecasting can lead to an important element in tourism industry to ensure that each investment by individuals, companies and government was worth it. From economy perspective, ecotourism is a growing business nowadays and can be an important indicator to the tourism industry. Hence, this study attempt to forecast the ecotourism product demand in Pahang based on number of tourist arrivals in National Park Kuala Tahan, Pahang. Box-Jenkins (Seasonal ARIMA) model is used to make analysis and forecast of the number of international and domestic tourist since 2013 until present. The accuracy and validation of the results is measured using mean absolute percentage error (MAPE). Results obtained by applying the proposed model and numerical calculation shows that Seasonal ARIMA models is effective for forecasting the number of tourist arrivals in National Park Kuala Tahan. The best model in forecasting ecotourism product demand in Pahang is $\mathrm{SARIMA}(0,0,1)(2,0,1)_{12}$ with MAPE value 13.92%.

Keywords: Ecotourism, Forecasting, Box-Jenkins, Tourism

INTRODUCTION

Tourism industry is one of the main economy indicators in the world and is growing very fast from day to day. According to The World Tourism Organization (UNWTO), tourism can be classified to 14 types such as cultural tourism, ecotourism, rural tourism, adventure tourism, health tourism, wellness tourism, medical tourism, business tourism, gastronomy tourism, urban and city tourism, mountain tourism, education tourism, sports tourism, and coastal, maritime and inland water tourism. In this study, we will focus on ecotourism industry as ecotourism industry received less attention among researcher. Ecotourism involved of natural, communities and sustainable travel. The International Ecotourism Society (TIES) defined ecotourism as responsible tourist to natural areas that maintain the environment, sustain the well-being of the local people and includes education. Pahang, which is located at East Coast Malaysia and the population around 5.1% from total Malaysian population always, be the tourist attraction because of its natural beauty of flora and fauna, covered by thousands of hectares of rainforest. Estimated exist more than 130 million year's old, national park located at Jerantut, gazetted as National Park since 1938, it is the largest national park more than 4000 square kilometers. The beautiful and unique natural scenery undeniable natural lovers around world. Based on this information, it can be seen that nature is the main source of tourism product in Pahang which lead to ecotourism product. Hence this study proposes to forecast the ecotourism product in Pahang. Thus, the discussion of this paper is organised as follows. The second section of this paper will discuss the selected literature review. The third section focuses on methodology used. The fourth section touches on empirical results and the final section concludes.

LITERATURE REVIEW

Tourism forecasting can lead to an important element in the tourism industry to ensure that each investment by individuals, companies and government was worth it. According to Song and Li [9], the number of tourist arrivals is a most popular measure for demand tourism. Past research has shown that modelling and forecasting tourism demand is numerous with various type of empirical analysis. ARIMA method is a famous modelling approach to forecast tourism industry. Many studies have applied this method such as Lim and McAller [7]. They suggested shorter forecast horizon is more accurate than a longer forecasting horizon for tourist arrivals in Australia when using ARIMA method. While Kim and Moosa [6] has modified direct and indirect method to forecast international tourist flows in Australia which result indirect method provides more accurate forecasts for than the direct method. On the other hand, Chu [2] forecast tourism demand by using ARMA models that is perform well when MAPE is lower than 2%. Besides that, Loganathan and Ibrahim [8] forecast international tourism demand in Malaysia by using Box-Jenkins SARIMA application and concluded smoothing techniques should be included

to forecast tourism demand. Song et al. [10] compared between Box-Jenkins, naïve and exponential smoothing via a web-based tourism demand forecasting the finding shows that accuracy of the judgmental forecast increased for the second round compared to first round. Scheyvens [11] proposed in her study of ecotourism and the empowerment of local communities, ecotourism should promote conservation and development at the local area. Besides that, local peoples can maximise their benefit by control over ecotourism places for their region and tradition. Dimitrov [3] assert model to estimate the size of rural tourism and ecotourism located near Bulgarian's border. Data was provided by local authority. The result indicated increment between 1416 and 1631 number of foreign visitor arrivals with lower MAPE value. Iasha et al. [4] estimated economic value for ecotourism product in west Sumatera, Indonesia. Data collected were primary data which is the questionnaire was developed using a dichotomous choice-questioning format. Result showed ecotourism visitor monopolized by the group of middle and highly educated people and average income for domestic visitor was Rp 2.5 million while international visitors were Rp 132.1 million. Since ecotourism give a lot of benefits to the tourism industry, researchers should focus on this area. There are few studies regarding ecotourism forecasting. Hence, this paper proposes to forecast ecotourism demand in Pahang using Box-Jenkins method.

METHODOLOGY

Time Series Model

According to Hanke and Wichern [4], Box-Jenkins methodology refers to a set of procedures to identify, fit, and check the ARIMA models with time series data and forecast that follows directly from the form of the fitted model. The extension to the autoregressive AR(p) and moving average MA(q) models is the mixed ARMA(p,q) model which has the form (Bowerman et. al [1]),

$$z_t = \delta + \varphi_1 z_{t-1} + \varphi_2 z_{t-2} + ... + \varphi_p z_{t-p} + a_t - \theta_1 a_{t-1} - \theta_2 a_{t-2} - ... - \theta_q a_{t-q}$$

Many observe that non-stationary time series exhibit certain homogeneity, which can be counted by making simple modification on the ARMA model called integrated processes. By adding and integrating process, the ARMA(p,q) model will become an ARIMA(p,d,q) namely autoregressive integrated moving average model, thus it writes as;

$$\varphi(B) z_i = \theta(B) a_i$$

where $\phi(B)$, the generalized autoregressive operator, is a polynomial of degree with exactly d zeroes equal to unity. Therefore;

$$\phi(B) = \varphi_p(B)(1-B)^d = \varphi_p(B)\nabla^d$$

where $\varphi_p(B)$ is a stationary autoregressive operator of order p.

Seasonal ARIMA (SARIMA) models are generalization of an ARMA model. Forecasting SARIMA can be expressed as ARIMA $(p,d,q)(P,D,Q)_n$. For P and p are the orders of autoregressive, D and d are the differences and Q and q are the orders of moving average value of non-seasonal and seasonal which is consist of values greater or equal to zero respectively. While, n^{th} refers to seasonal pattern of data. If the seasonal pattern monthly the n value will be 12, quarterly equal to 4.

Box-Jenkins methodology consists of five-step iterative procedures as follows:

Step 1: Removal of Non-stationary Components: The first step in model identification is to determine whether the series is stationary or non-stationary. The stationary of data can be determined by looking at autocorrelation function (ACF) and partial autocorrelation function (PACF). If the model is non-stationary, differencing will be used to convert it to stationary model.

Step 2: Model Identification: The selection of an appropriate model is generally a complicated task. Analysis of the historical data is used to identify an appropriate Box-Jenkins model by looking at their ACF, PACF, stationary, and seasonality behavior if any.

Step 3: Estimation: After selecting the tentative model, the parameter will be estimated. The estimation method used is ordinary least square method with available historical data.

Step 4: Diagnostic Checking: Various diagnostic checking especially analysis of residual are used to check the adequacy of the tentatively identified model and, if need be, to suggest and improve as a tentatively new identified model. In diagnostic checking, we look at the residual plot of the autocorrelations.

Step 5: Forecasting: Once the final model is obtained, the forecasting process for future will be conducted.

Data

This study used a 5-year monthly data of tourist arrival at National Park Kuala Tahan, Pahang. Therefore, the data is obtained from Department of Wildlife and National Parks Peninsular Malaysia. This study focuses on total number of tourist entered the National Park Kuala Tahan from January 2013 until December 2017.

EMPIRICAL RESULTS AND DISCUSSIONS

Seasonality means a pattern data related to the calendar and repeated over a particular time. Seasonal can be defined as a pattern of change that repeats itself year after year (Hanke et al [4]). The data from January 2013 until December 2017 with seasonal effect of monthly basis is shown clearly in Figure 1.

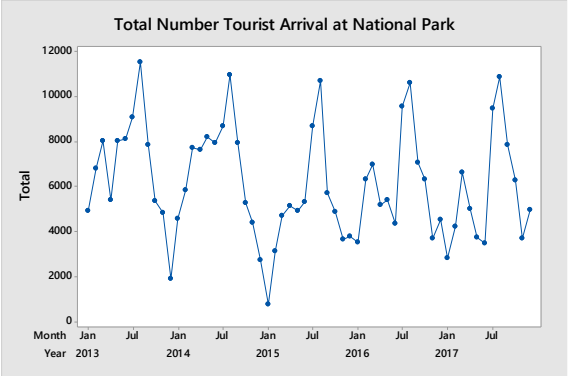

Fig. 1 Number of Tourist Arrivals at National Park from 2013 to 2017

Number of tourists came to National Park clearly depends on seasonal pattern. There are peak number of tourists on July every year and decreasing at the end of year because of monsoon season during that time. Thus, we begin first step in SARIMA that is model identification by looking at ACF and PACF as shown in Figure 2a and 2b.

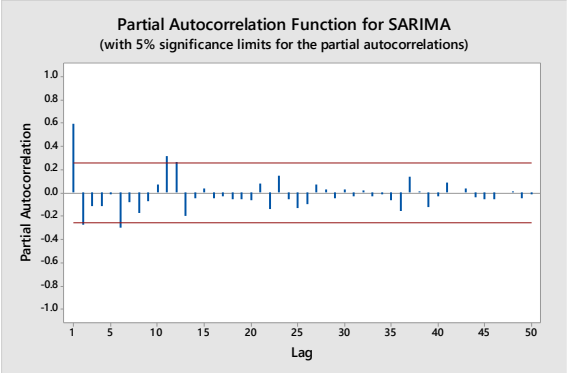

Fig. 2a PACF for non-stationary data

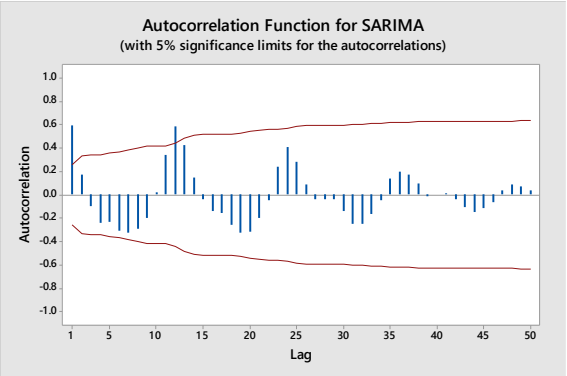

Fig. 2b ACF for non-stationary data

Figure 2a and 2b shows PACF and ACF for non-stationary data respectively. For non-seasonal (p,d,q) PACF pattern, there are spike at first 2 lags and tend to dies out pattern which indicate AR (2). As for ACF, only lag 1 spike and trail off to zero gradually after lag 2 which is indicate MA (1) behavior. PACF for seasonal (P,D,Q) which indicate autoregressive shown there are spike in lag 1, 2, 12, and 13, in addition there were small blip for lag 24 and 36. This suggested the series was monthly seasonal. This behavior also suggests AR (2) term at the seasonal lag 12. While ACF indicates there were significant spike at lag 1 and 12 then dies out. This is consistent with MA (1) pattern. Since the data are influenced by seasonal pattern, a trend pattern exists and trend is not a stationary. Therefore, the data can will be transform into stationary series by differencing. The seasonal differenced are computed as Figure 3.

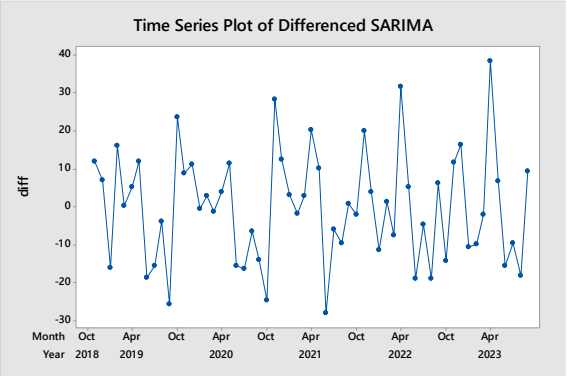

Fig. 3 Time Series plot first differencing

Figure 3 shows time series plot after differencing for SARIMA. The time series plots satisfy the stationary condition since means and variance are constant over time. The ACF and PACF for the differenced series are presented in Figure 4a and 4b.

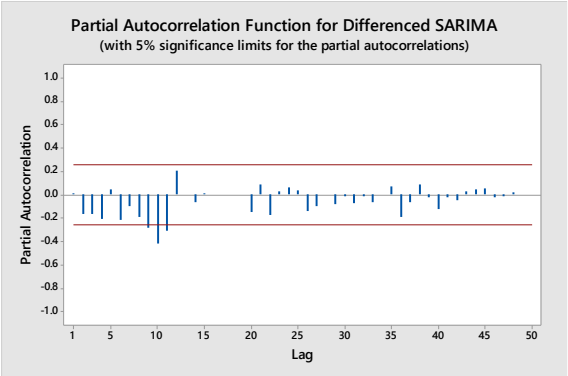

Fig. 4a PACF first differencing

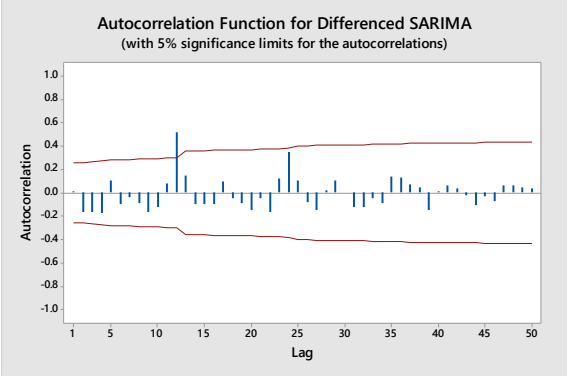

Fig. 4b ACF first differencing

The PACF have one significant spike at lag 10 then dies out, and the ACF have significant spike at lag 12 and 24 tend to follow die down pattern, it is indicating seasonal pattern of AR (0), AR (1) and MA (2). At non-seasonal level, the PACF and the ACF dies out indicate AR and MA behavior of (1). Hence, we tend to estimate model by using information of PACF and ACF earlier. The tentative models stated as Table 1.

Table 1 SARIMA tentative model

SARIMA	
$(2,0,1)(2,0,1)_{12}$	$(1,1,0)(1,1,2)_{12}$
$(1,0,1)(2,0,1)_{12}$	$(0,1,1)(0,1,2)_{12}$
$(1,0,0)(2,0,1)_{12}$	$(1,1,1)(0,1,2)_{12}$
$(0,0,1)(2,0,1)_{12}$	$(1,1,0)(0,1,2)_{12}$
$(1,1,1)(1,1,2)_{12}$	$(0,1,1)(1,1,2)_{12}$

The standard procedure for model estimation involved parameter estimation by using least square method for tentative models. The parameters are not significant if the *p-value* greater than 0.05. Based on the estimation results, from 10 models only 6 models are significant and can proceed to next step. After the estimation process, diagnostic tests have been applied to the six models to check the adequacy. The result is shown in Table 2.

Table 2 Ljung-Box Result for Model of SARIMA

Model	Ljung-Box Value	Result
SARIMA $(1,0,0)(2,0,1)_{12}$	0.051	Significant
SARIMA $(0,0,1)(2,0,1)_{12}$	0.079	Significant
SARIMA $(1,1,0)(1,1,2)_{12}$	0.319	Not Significant
SARIMA $(0,1,1)(1,1,2)_{12}$	0.179	Not Significant
SARIMA $(1,1,1)(0,1,2)_{12}$	0.256	Not Significant
SARIMA $(1,1,0)(0,1,2)_{12}$	0.368	Not Significant

LBQ for each model stated whether models are significant or not significant. If the result of LBQ values greater than 0.05, it indicates the model is not significant. Thus, we eliminated 4 models which are not significant because their large LBQ values. Only SARIMA $(0,0,1)(2,0,1)_{12}$ and SARIMA $(1,0,0)(2,0,1)_{12}$ are adequate. Then, we generate forecasts for sixty periods to compare values of forecast error. Mean absolute percentage error (MAPE) is used as forecast accuracy; SARIMA $(1,0,0)(2,0,1)_{12}$ generated 8.77% and SARIMA $(0,0,1)(2,0,1)_{12}$ 8.61%. Table 3 shows result for MAPE for both models.

Table 4 MAPE Result for Model of SARIMA

Model	MAPE Result
SARIMA $(1,0,0)(2,0,1)_{12}$	8.77%
SARIMA $(0,0,1)(2,0,1)_{12}$	8.61%

Figure 5 shows time series plot for both models SARIMA. Both models have slightly different forecast values middle of 2015. Thus, for seasonal ARIMA $(0,0,1)(2,0,1)_{12}$ was selected as best model since values of MAPE are lowest compared to

SARIMA $(1,0,0)(2,0,1)_{12}$.

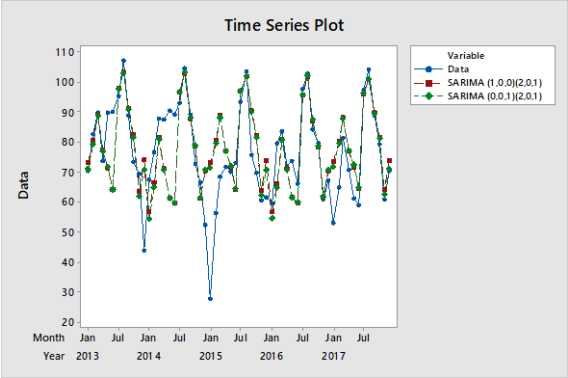

Fig. 5 Time Series Plot for SARIMA $(0,1,1)(1,1,2)_{12}$

CONCLUSIONS

This study found that SARIMA $(0,1,1)(1,1,2)_{12}$ is the best model to capture seasonality effect in forecasting number of tourist arrivals at National Park Kuala Tahan, Pahang. Forecasting number of tourist in National Park can help Malaysian government as well as stakeholder in tourism industry to perform better strategic planning and to help them in maximizing profits. This study shows that Box-Jenkins method has the ability to forecast number of tourists accurately. Since this study only focuses on SARIMA models, further researches can be conducted using other forecasting methods. Given the difficulty of finding a largest data, further researches could focus on largest set of data which may help to identify the best models. The analysis on the comparison between local and foreign tourist could be an interesting research analysis.

ABSTRACT

Regarding a moving towards development with no threat to our future generations, an overwhelming consumption of natural resources is the dominant sustainability and environmental concerns argued either in international or national conferences. In particular, to heavily seek for high potential solutions in minimizing environmental impacts, building sector should firstly be considered practically since it is responsible for almost forty percent of both global energy and materials used and contributed around one-third to global greenhouse gases emission. This research, therefore, is aimed at evaluating a level of embodied carbon emissions derived from building construction materials, using educational institutes as case studies to represent an environmental performance of construction materials based on reinforce concrete structure in tropical climate. The results reveal that on weighted average, mass intensity and embodied carbon intensity of construction materials are 1,627 kg/m^2 and 322 kgCO_2/m^2. In addition, the taller the building height the more it is likely to help improve such intensities. Almost 90% of mass intensity contributed to structural component materials whereas the embodied carbon emissions attributed 69% to structural component materials and 24% to decorating component materials. The results also indicate that the building with reinforce concrete structure might focus only on six materials namely concrete, steel, aluminium, cement, paint, and ceramic tile since the contribution of such materials to embodied carbon emission do account for 94%. The findings will be useful for planning proactive strategies in mitigating embodied carbon of building to cope with the challenges of global warming in the future.

Keywords: Embodied carbon emission, Educational building, Building materials, Construction phase, Reinforce concrete structure

INTRODUCTION

Globally, building sector has played an important role in a moving towards sustainable development goals as it accounted for 40% of energy consumption, 40% of raw materials use, 12% of potable water consumption, one-third of carbon emission and 40% of waste to landfill [1,2]. Formally, numerous studies of buildings mostly focused on the operation phase in order to reduce energy consumption which will be consequently decreased an amount of carbon emission [3]. However, the construction phase performances should take into consideration since the amount of material used for building construction will proportionally affect the level of total building's embodied carbon and different types of building material will additionally result in different amount of energy demand in operation phase [4,5].

In Thailand, even a quarter of construction permission of commercial buildings was found to be school and institutions, merely less than one percent of such number is regulated under the energy conservation act [6,7]. A million of resources is prioritized for educational system with aiming to enhance capacity building and support the needs of the country whilst an efficiency of resources consumption is not considered significantly.

This study, therefore, aimed at evaluating a level of embodied carbon emissions derived from building construction materials of buildings located in educational institute in Thailand and identifying the key materials effecting a proportion of embodied carbon intensity in order to propose the alternative solutions for minimizing environmental impacts throughout building service life. The findings will be useful for building owner or decision maker in designing a sustainable building based on low carbon approach and in planning proactive strategies in mitigating embodied carbon of building to cope with the challenges of global warming in the future.

METHODOLOGY

Cases Description

Four buildings with different purpose of Chulalongkorn University located in Bangkok were assessed to evaluate the environmental performances through mass intensity and embodied carbon emission. All building cases were built based on reinforce concrete structure. Three of them were classified as a mix-used building with total floor area of 16,143 m^2, 21,627 m^2 and 3,225 m^2 for Building A (12-storey building served with conference rooms, classrooms, laboratory rooms, research units, gym), Building B (13-storey building occupied with classrooms, conference rooms, offices and a cafeteria) and Building C (2-storey building with a cafeteria on the ground floor and an information center on the first floor) respectively, whilst the last was a 17-storey dormitory building (Building D) with total floor area of 31,500 m^2. Due to a difference in building size, in order to be comparable, a square meter of floor area was used as a functional unit to quantify each building's performances.

Building Materials Analysis

Regarding building construction components, the construction materials in this study were classified into four categories named structural materials (SM), decoration materials (DM), materials supplied for ventilation and air condition (VA) system, and for sanitary and fire protection (SF) work. To analyze building construction performance, either data of material types or number were obtained from bill of quantities. In particular, twenty different types of building material that commonly used in building construction were addressed, then a record of each material number was calculated in term of kg/m^2 as demonstrated in equation 1.

$$MI = \sum_{j=1}^{4} \sum_{i} (Q_i \div A) \quad (1)$$

Where MI – the mass intensity (kg/m^2) represents the consumption rate of construction materials, Q – Quantity (kg) represents an amount of material used, A – area (m^2) represents a total floor area of building, i refers to the type of materials, and j refers to the four class of construction component.

Carbon Emission Assessment

Embodied carbon emission of building is an emission arose from a consumption of all materials used for building construction. A boundary of such emission calculation involves raw material extraction, transportation from raw material site to material production plant, and production process of material. Due to a lack of available data in Thailand, however, the BEES (Building for Environmental and Economic Sustainability) database was used as an emission factor (EF) to determine the embodied carbon emissions as demonstrated in equation 2.

$$ECI = \sum_{j=1}^{4} \sum_{i} (MI_i \times EF_i) \quad (2)$$

Where ECI - the embodied carbon intensity ($kgCO_2/m^2$) represents the carbon emissions rate of construction materials and EF – the emission factor ($kgCO_2/kg$) refers to the corresponding embodied carbon coefficient of materials.

RESULTS AND DISCUSSION

Mass Intensity

Table 1 illustrated values of MI of reinforce concrete building in a range of 1,595 – 2,252 kg/m^2 which meant in every square meter of building floor area, more than fifteen thousand of building materials were consumed in this study. In addition, because of a complexity of scientific laboratory room design, a greater amount of construction material required rather than the other conventional rooms, resulting in the highest MI revealed in Building A. The proportion of mass intensity on weighted average classified by building construction components and materials type revealed that the largest share of material used contributed to SM component with the major source of various concrete types used for sole plate, foundation, structure and precast as illustrated in Fig. 1. The finding was in agreement with the data discoursed in previous study [5,8].

With an exclusion of Building A, high-rise building (Building B and D) seem to exhibit more environmental-friendly performance in term of resources depletion since such buildings required slightly less resources per functional unit than low-rise building (Building C) even the total resources consumption would be higher. Moreover, a consumption of materials in DM component also emphasized that MI value of such component in Building C was almost twice more than the value presented in the other buildings which was mainly influenced by the consumption of cement group for wall finishing. Although a consumption of materials in DM component is uncontrollable since it is heavily determined by individual satisfaction, however, to reduce such environmental performance, a loft design building, a building polished with neither ceramic tile nor paint, was recommended as it could reduce nearly 4% of total mass intensity (Fig.1).

Embodied Carbon Intensity

Based on weighted average with an exclusion of Building A, an intensity of embodied carbon in building construction materials in this study was 347 $kgCO_2/m^2$. As similar to the result of MI, apart from Building A, Building C showed the higher point of

ECI than Building B and D. It could be concluded that, a smaller floor area is, a larger amount of embodied carbon intensity presents. The finding was in disagreement with the research on embodied carbon emission of office building in China, which concluded that the higher buildings area, the larger number of carbon emissions per unit area emitted [9]. However, that study was focused on the comparison between multi-story building, high-rise building and super-high-rise building, which this research was an investigation of small building and high-rise building. Therefore, it might be implied that difference in height of building has significant contribution in global warming in different range.

In addition, whilst a category of SM component was employed for more than 70% of total embodied carbon emission, about one-fourth of such intensity was associated with DM component. As presented in Fig 2, the two major materials generated a great amount of carbon emission were a group of concrete (44%) and aggregate (34%). To reduce carbon emission embodied from structural materials, a suggestion for new building construction, fly-ash or blast furnace slag are encouraged to substitute instead of using virgin cement, mortar, or concrete [10].

A Relation of Mass and Embodied Carbon Intensity

Excluding construction materials in a group of concrete which shared the highest contribution either in building material profile or in the embodied carbon content as mentioned above, Fig. 2 presented a contribution of ten building construction materials to the total mass or embodied carbon intensities in the bar chart.

Table 1 Mass and carbon intensities of major construction materials in educational buildings

Unit: Mass intensity (kg/m^2), Embodied Carbon Intensity ($kgCO_2/m^2$)

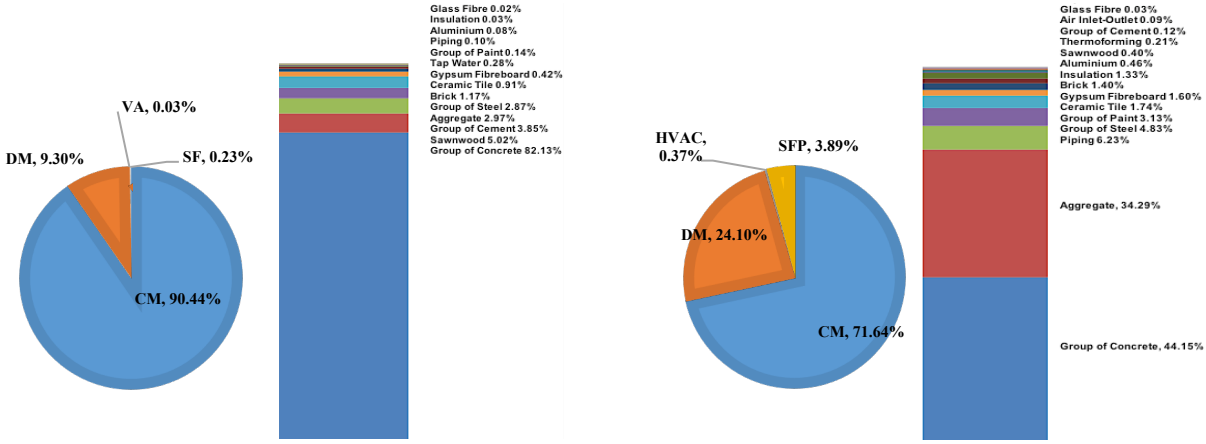

Fig. 1 Proportion of mass (left) and embodied carbon (right) in construction materials

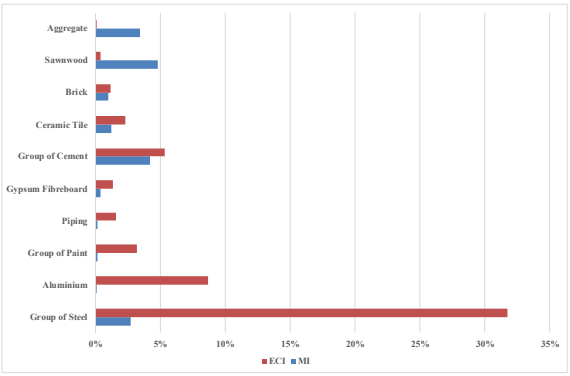

Fig. 2 Contribution of building materials to mass and embodied carbon intensities

The result revealed that there were three kinds of relation among the contribution of materials to both variables. Firstly - high consumption material with high emission, similar to a group of concrete, the high contribution was found in a group of cement and ceramic tile to both material mass and embodied carbon. Secondly – high consumption material with less emission, sawnwood and aggregate highly contributed to the total mass (3-4%) with insignificant in contribution to the embodied carbon (less than 0.4%). Lastly – less consumption material with high emission, due to its high embodied carbon efficient of steel, brick, gypsum fiberboard, aluminium, paint, and piping, even such materials were less consumed in construction process, its contributed greatly amount of carbon emission. Therefore, considering possible alternatives for alleviating global warming through building sector should involve either high carbon emitting materials or mass materials. Based on the results of this study, the building with reinforce concrete structure should focus on six materials namely concrete, steel, aluminium, cement, paint, and ceramic tile since the contribution of such materials to carbon emission accounted for 94% of the total embodied carbon. To roughly estimate building coefficient, a specific carbon emission of building based on reinforce concrete structure in Thailand was 0.198 $kgCO_2/kg$ of material mass.

A Comparison of Embodied Carbon Intensity with Other Studies

A comparison of embodied carbon intensity between the results of this study and the previous findings was presented in Table 2. Based on the same building typology, it was found that the ECI of this study was lower than the other cases. It might be because of the newly innovation and advance technology that has been developed occasionally from the past and the impact of the more total floor area that resulting in the decreasing of embodied carbon emission. However, by considering the concept of zero emission building (ZEB), it could be implied that to moving towards low carbon society, all new building construction should be designed based on such theme since the building will emit zero emission during the operation phase whilst the contribution to carbon profile during the construction phase will be compromised with the benefits gained of the utilization of building waste after its end-of-life stage.

Alternative Insulation Materials for Improving Environmental Performance of Existing Building

For improving existing building, energy efficiency performance was mainly focused on and energy simulation was introduced to anticipate the changing of energy consumption in building after implementation. Since more than half of total energy used in building in tropical countries is supplied for cooling system, various kinds of external wall insulation, therefore, were selected to examine an amount of energy-related emissions that will be reduced and to identify the best solution for optimizing energy-related emissions throughout a

[a]Assumed all insulation life time of 10 years.
[b]Wall area for insulation installation in entire building is 7,027 m^2 and wall insulation thickness is 100 mm for all cases, except aerogel (50 mm)
[c]Building service life (BSL) is 50 years, thus 5 sets of insulation were installed throughout BSL.
[d]CO_2 emission due to electricity use in Thailand is 0.5664 $kgCO_2/kWh$ [17]

building service life of 50 years. In this study, Building A was selected to simulate energy use through EnergyPlus 8.8.0 model.

The results revealed that implementing all external wall insulation types certainly reduce energy required during building use phase since it helps lesser heat gain through building from the outside, and different types of external wall insulation showed no difference in the amount of energy saving. The best option of external wall insulation in reducing carbon emission for entire building service life was cellulose followed by glass wool and Polyurethane. Whilst aerogel insulation showed no gain in reduction potential because of its high embodied carbon coefficient, as demonstrated in Table 3.

For entire building service life, installation of cellulose insulation could reduce about 1,164 tCO_2e due to the energy saving during use phase. Such number can be used to compensate for the amount of embodied carbon increased in building due to the increase of material (insulation) consumed, the payback period of carbon offset was 1.4 years for every 10 years of insulation replacement.

CONCLUSION

As the global trend is moving towards nearly zero carbon building, this study is aimed at quantifying the amount of embodied carbon in construction materials and identifying the key materials effecting a proportion of embodied carbon intensity in order to propose the alternative solutions for minimizing environmental impacts throughout building service life. Buildings located in Thai academic institute were used to demonstrate the intensities of materials mass and embodied carbon. The results illustrated that on weighted average, the intensities of mass and embodied carbon in building construction materials were 1,627 kg/m^2 and 322 $kgCO_2/m^2$. In addition, in term of building size, high-rise building was found to contribute to both intensities less than low-rise building. To roughly estimate building coefficient, a specific carbon emission of educational building in Thailand was 0.198 $kgCO_2/kg$ of material mass.

The findings also indicated that either mass or embodied carbon intensities had contributed the highest share to structural material component, followed by decoration materials component, materials supplied for sanitary and fire protection work and for ventilation and air condition system respectively. Moreover, in order to mitigating embodied carbon of building, two group of materials that should be focused on were a group of high

embodied carbon efficient materials and a group of materials used in huge number.

For improving existing building, a solution for reducing energy consumption in cooling system was investigated as it requires the highest loads of energy. The result of energy simulation from applying four different external wall insulations revealed that even all insulations provide a better benefit in term of less energy consumption required during operation phase compared to Base case, however, when considering the entire building service life of 50 years, installation aerogel insulation has failed to improve building performance because of its high embodied carbon coefficient.

The characteristic of all buildings in this study is very similar to most of typical buildings in Thailand since the material used for foundation and structure was based on reinforce concrete and the envelope pattern was an opaque wall constructed from brick. The findings of this study therefore could be widely applied to the other buildings. The initiative of reducing carbon emissions of building sector either on loft style building or on zero emission building could lead to sustainable consumption and production in Thailand, enabling the country in moving towards low carbon society successfully as planned.

ACKNOWLEDGMENT

The authors thank the Thailand Research Fund through the Royal Golden Jubilee Ph.D. Program (Grant No. PHD/0071/2559) for student financial support as well as the Office of Higher Education Commission (OHEC) and the S&T Postgraduate Education and Research Development Office (PERDO) for the financial support of the Research Program. We also would like to express our sincere thanks to the Faculty of Engineering, Chulalongkorn University, and the Center of Excellence on Hazardous Substance Management (HSM) for their invaluable supports in terms of facilities and scientific equipment.

THE EFFECTIVENESS OF FLOOD OCCURRENCE COUNTER MEASURE PLAN DUE TO LOCAL CONDITION

Agus Suharyanto
Faculty of Engineering, Universitas Brawijaya, Indonesia

ABSTRACT

Kali Bogel river is a river flowing in Blitar regency, East Java province, Indonesia. The outlet of the river is located in Brantas river with river long of Kali Bogel is 25 km. The river mouth is located between two dams i.e. Wlingi dam and Lodoyo dam. The distance between two dams is 10 km. Consequently, in the rainy season most of the water level of Kali Bogel river mouth is lower than water level of Brantas river. The submerge flow almost occurred in river mouth during rainy season. Therefore, in rainy season almost every year the floods were occurred in the area beside of Kali Bogel river. The main reason is the water from Kali Bogel river cannot flowing smoothly to the Brantas river and consequently the overflow were occurred at many river bank. There are some plans were done to minimize the flood occurrences. Among them are normalized the river channel dimension, constructing small dams in upper stream area, and finally constructing floodway to minimize the submerge flow occurred in the river mouth. In this paper the effectiveness of three plans due to the civil work and social impact were discussed. The advantages and disadvantages of each plan was analyzed base on hydraulic – hydrologic conditions and will be described in this paper. Finally, it can be found that floodway is the best recommended to minimize the flood occurrences in Kali Bogel river but costly and have little bit high social impact.

Keywords: Flood, Small dam, Floodway, Return period, submerge flow.

INTRODUCTION

Flood is one of natural phenomenon which can be occurred in many places. There are many reasons of flood occurrences. Among them are high intensity of rainfall, not enough channel dimension, and watershed condition [1]. To minimize the flood occurrence, the several method can be applied due to the local condition. Evaluating of channel dimension, development of small dam, and applied of floodway can be used as counter measure method to minimize the flood occurrence. Evaluating of the channel dimension normally have result to enhance the channel dimension. If the land beside of channel still available, this method is easy and cheaper one. Due to the land availability, in area have high density population, this method is difficult to apply.

The second method is developed the small dam in upper stream area to hold the runoff discharge. If the runoff discharge can be hold until peak discharge at the reservoir, the flood occurrence can be minimized. The amount of reducing peak discharge is depend on the reservoir volume [2]. The reservoir volume design is depend on the topographic condition. Therefore, this method is fully depend on the local condition. If this method is effective to minimize the flood occurrence, the budget to construct the small dam is expensive.

The third method for minimizing flood occurrence usually is floodway. This method is easy to evaluate and easy to apply, but need land and budget consuming for constructing. This method is very common as the last alternative to reduce the flood occurrence especially in urban area or in area with special condition.

Kali Bogel river is one of a river located in Blitar regency, East Java province, Indonesia. This river as tributary of the biggest river in East Java province namely Kali Brantas river. The outlet of Kali Bogel river is located between two dams namely Wlingi and Lodoyo dams. These dams are located in Kali Brantas river and separated about 10 km distance. Wlingi dam is upper side of Lodoyo dam. Because of two dams only separated by 10 km distance, the high water level is occurred along the year in channel between these two dams. Due to this condition, the submerge flow is almost occurred at Kali Bogel outlet during rainy season. Consequently, the flow from Kali Bogel have big obstacle and back water occurred along the river. Due to this condition, flood almost occurred along Kali Bogel river especially during raining season. In this paper, the most effective plan based on the local condition as counter measure of the flood occurrence of Kali Bogel will be discussed. The hydrologic and hydraulic formulas were applied in channeling, dam construction plan, and floodway design analyses.

The counter measure of the flood occurrence of Kali Bogel river still in the plan stage. The implementation of the plan will be done in the near future. This research result is take account as consideration to decide which method will be implemented to minimize the flood.

RESEARCH AREA

The research area is Kali Bogel river. This river located in Blitar regency, East Java province, Indonesia. The location of research area can be shown in Fig.1. The Kali Bogel river have long 25 km and the watershed occupied 55,000 ha or 55.5 km^2. The outlet of Kali Bogel is located between two dams namely Wlingi dam in upstream and Lodoyo dam in downstream. The distance between two dams is about 10 km. The outlet of Kali Bogel river is separated about 2.3 km from Lodoyo dam to Wlingi dam direction. The layout of Kali Bogel watershed and river network is shown in Fig. 2.

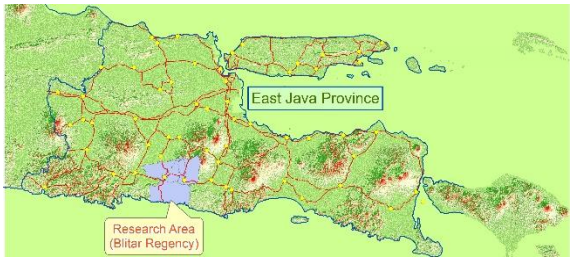

Fig.1 Location of research area.

Fig. 2 Layout of Kali Bogel watershed.

MATERIALS AND METHODS

The materials used in this research are topographic map in scale 1:25,000, remotely sensed satellite imageries, rainfall intensity data, soil map, and channel cross sectional data. From the topographic map, the watershed boundary, river network, river long, and watershed slope were analyzed. The remotely sensed satellite imageries is used to generate the land use map. The maximum daily rainfall intensity was selected for each rainfall station gauge along 10 years. The suitable statistical method is used to analyze the rainfall intensity with certain return period. The soil map in scale 1:25,000 was collected from Agriculture agency, East Java province government. The cross section data with interval 50 m was surveyed directly to the field. Base on the collected data, the channeling analyses, small dam plan, and floodway plan were done to minimize the flood occurrences. The analyses methods of each will discussed in the next paragraph.

Channeling Analysis

Flood can be occurred caused by the channel dimension is not enough to receive the runoff discharge. Therefore, the channel dimension should be increased until the water level is not over topped through the channel bank. In this research, the runoff discharge was analyzed using Nakayasu Synthetic Unit Hydrograph (SUH) [3]. The channel dimension was analyzed using Manning's continuity equation [4].

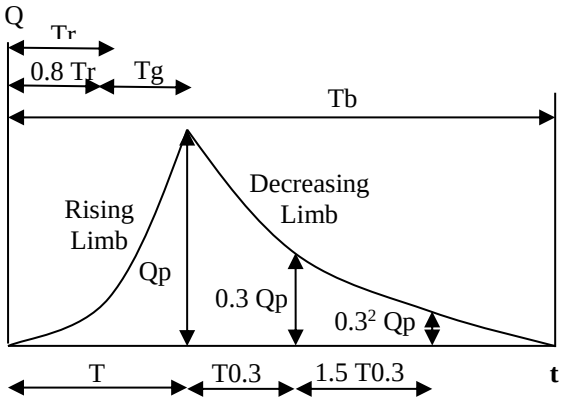

Fig. 3 Typical Hydrograph of Nakayasu SUH.

$$Qp = \frac{C.A.Ro}{3.6(0.3Tp.T0.3)} \quad (1)$$

$$Qa = Qp\left(\frac{t}{Tp}\right)^{2.4} \quad (2)$$

Where:

Qa	= rising limb discharge (m^3/se.)
t	= time (sec. or hour)
Qp	= peak discharge (m^3/sec.)
C	= surface runoff coefficient
A	= watershed area (km^2)
R_o	= rainfall unit (mm)
T_p	= time to peak (hour)
$T_{0,3}$	= time need in decreasing from peak discharge to 30% of peak discharge.

The part of decreasing limb can be calculated using eq. 3 - 5.

$$Qd > 0.3Qp \qquad Qd = Qp.0.3^{\frac{t-Tp}{T0.3}} \quad (3)$$

$$0.3Qp \geq Qd > 0.3^2 Qp \qquad Qd = Qp.0.3^{\frac{t-Tp+0.5T0.3}{1.5T0.3}} \quad (4)$$

$$Qd \leq 0.3^2 Qp \qquad Qd = Qp.0.3\frac{t-Tp+1.5.T0.3}{2.T0.3} \quad (5)$$

$$Tp = tg + 0{,}8\ tr \quad (6)$$

If L < 15 km, $tg = 0{,}21\ L^{0,7}$ (7)
If L > 15 km $tg = 0{,}4 + 0{,}058\ L$ (8)
where:
L = length of channel (km)
tg = time concentration
tr = 0,5 tg to tg (hour)
$T_{0,3}$ = α tg (hour)
tr = flood unit time (hour)
α = hydrograph parameter

$$\alpha = \frac{0.47(A.L)^{0.25}}{tg} \quad (9)$$

The rainfall intensity usually recorded in daily data. Due to the data requirement to analyze the runoff discharge, it is necessary to convert the daily to hourly rainfall data. The Mononobe formula is used in this analysis. The formula can be shown in eq. 10 [5].

$$I = \frac{I_{24}}{24}\left[\frac{24}{t_c}\right]^{2/3} \quad (10)$$

Where:
I = rainfall intensity (mm/hour)
R_{24} = daily rainfall intensity (mm/day)
tc = rainfall duration

By using peak runoff discharge and channel geometry as input data, the water level in channel is analyzed using hydraulic formula such as Manning's continuity equation. The HEC-RAS software was applied in channel water profile analysis.

$$V = \frac{1}{n} S^{1/2} R^{2/3} \quad \text{and} \quad R = A/P \quad (11)$$
$$Q = V \cdot A \quad (12)$$

Where:
Q = Discharge (m^3/sec.)
V = Velocity of flow in channel (m/sec.)
S = channel slope
R = wetted radius (m)
A = channel cross sectional area (m^2)
P = wetted perimeter (m)

Small Dam Plan

The location of dam was selected based on topographic condition. The deep reservoirs with narrow inundated area is better than the shallow reservoir with broad inundated area. Consequently, deep reservoirs with small inundated area usually can be found in the upstream area. The dam capacity was evaluated using water balance equation. The equation can be shown in eq. 13.
$St = St\ (t-1) + lt - Ot - Et - Lt$ (13)
and $0 < St < C$

where:
C = effective dam capacity (m^3)
St = intercept water volume in t period (m^3)
St (t-1)= intercept water volume in t-1 period (m^3)
lt = river discharge inflow in t period (m^3/sec.)
Ot = outflow discharge in t period (m^3/sec.)
Et = reservoir evaporation in t period (m/sec)
Lt = discharge loses in t period

Floodway

Floodway is designed to reduce the discharge flowing through the existing channel. If the existing channel dimension is not enough to receive the runoff discharge in spite of the others effort to reduce the runoff discharge was applied, finally the floodway will be applied. The design of floodway is depend on the local condition. Channel alignment are depend on the topographic condition and land availability. Channel dimension is depend on the amount of runoff discharge want to reduce from the discharge flowing through the existing channel. HEC RAS software will be used to analyze the hydraulic properties. The principle model of floodway is shown in Fig. 4. Basically, the continuity equation as shown is eq. 11 and 12 and energy equation in steady flow condition at open channel were used to analyze the channel dimension. The standard step is applied to analyze the water level profile. The energy equation in steady flow condition is shown in eq. 14 [6].

$$h_1 + \alpha_1 \frac{U_1^2}{2g} + z_1 = h_2 + \alpha_2 \frac{U_2^2}{2g} + z_2 + h_f + h_e \quad (14)$$

Where:
h = water depth (m) α = velocity coefficient
U = average velocity (m/sec.) z = elevation (m)
g = gravitation (m^2/sec.)
hf = friction energy looses
he = energy loses (cross section change)

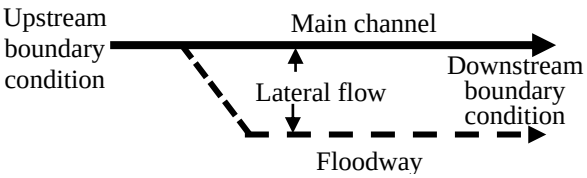

Fig. 4 Floodway model by HEC-RAS

RESULTS AND DISCUSSION

Six sheets of topographic maps in scale 1:25,000 were used in this research. From these maps the watershed boundary, length of main river, river network, others physical watershed data were found. The area of watershed is 55,000 ha and the length of main river is 25 km. There are four rainfall stations affected to the Kali Bogel watershed, namely Lodoyo, Judeg, Kanigoro, and Bacem stations. The 10 years daily rainfall data from 2004 to 2013 were collected. From the four location of rainfall stations, the

Thiessen polygon was drew to analyze the average rainfall in Kali Bogel watershed. The maximum daily rainfall from the each rainfall station can be shown in Table 1. By using the Thiessen polygon, the average rainfall for each year was analyzed. Table 2 is shown the average rainfall of Kali Bogel watershed.

Table 1 Maximum daily rainfall data

Year	Maximum daily rainfall (mm)			
	Lodoyo sta.	Judeg sta.	Kanogoro sta.	Bacem sta.
2004	289.67	288.68	264.33	276.63
2005	113.87	115.67	114.35	114.65
2006	87.50	87.25	86.75	85.95
2007	103.86	104.67	66.00	80.32
2008	23.25	58.95	59.75	40.25
2009	16.25	36.00	37.25	44.25
2010	26.50	25.50	30.00	47.50
2011	16.00	57.00	39.00	33.25
2012	20.25	39.75	55.75	57.50
2013	66.00	68.15	69.00	66.15

Table 2 Average maximum daily rainfall

No.	Year	Av. Maximum rainfall (mm)
1	2004	289.67
2	2005	115.67
3	2006	87.50
4	2007	104.67
5	2008	59.75
6	2009	44.25
7	2010	47.50
8	2011	57.00
9	2012	57.00
10	2013	69.00

Based on the average maximum daily rainfall data, the statistical distribution data was tested. The Log Pearson type III distribution is the best fit for this sequence data. By using this distribution formula, the daily rainfall data with several return periods were analyzed. Finally, the rainfall data in Kali Bogel watershed with several return periods can be shown in Table 3. To calculate the runoff discharge using Nakayasu SUH, the hourly rainfall data is needed. Therefore, the daily rainfall data as shown in Table 3 was convert to hourly rainfall using Mononobe formula. Base on the rainfall data from each rainfall station, the rainfall duration can be decided is equal to six hours. Consequently, the daily rainfall data was converted to hourly data for six hours rainfall duration. The hourly rainfall data after converted from daily rainfall data using Mononobe formula can be shown in Table 4.

Table 3 Daily rainfall data with many return periods

No.	Return period (year)	Rainfall intensity (mm/day)
1	2	68.37
2	5	115.06
3	10	165.16
4	20	224.12
5	50	365.66
6	100	509.33

Table 4 Hourly rainfall data

Time	Return periods rainfall (mm)			
(hour)	2 years	5 years	10 years	20 year
1	26.32	44.30	63.59	86.29
2	6.84	11.52	16.53	22.43
3	4.79	8.05	11.56	15.69
4	3.83	6.44	9.25	12.55
5	3.21	5.40	7.75	10.51
6	2.87	4.83	6.94	9.41

After finishing the rainfall data, the next step is analyzed runoff occurrence. Runoff data was analyzed using Nakayasu SUH as shown in eq. 1 to 9. With 55,000 ha area of watershed, 25 km river length, 0.7 runoff coefficient, and rainfall data as shown in Table 4, the runoff occurrence was analyzed. From the analyzed results the time to peak and peak discharge of rainfall data with return periods 2 and 5 years are 1.5 hours, 2 hours, 200.31 m^3/sec., and 331.44 m^3/sec., respectively. This data as main input data to simulate the water level profile in the channel using HEC-RAS software. The location of cross section area using in this research is shown in Fig. 5. In this figure, the red points are indicated the location of cross sections to check the water level from the simulation results. In this paper only cross section in point 18 is discussed. The simulation result of water profile using HEC-RAS in point 18 can be shown in Fig. 6. From this figure it can be concluded that the flood in Kali Bogel river will be occurred if the rainfall is bigger or equal than rainfall intensity with return period 5 years. The water level in point 18 is 2 m higher than river bank. For point 16, the water level is 1.2 m higher than river bank.

To reduce the water level, the river channeling was proposed. From the existing cross sectional dimension, to reduce the water level until under river bank level it is necessary to dike 0.75 m deeper and 1.5 m wider of channel width. To increase the channel cross sectional dimension a long river length, about 750 thousand US$ is needed. Base on the topographic situation, the location of points 11 to 15 is located in lower area. Therefore, after channeling, the flood still occurred in this area.

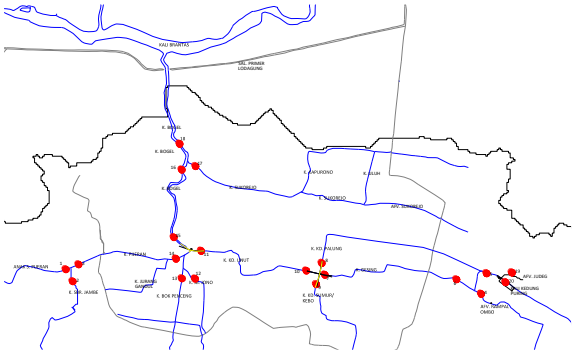

Fig. 5 Points of cross section area.

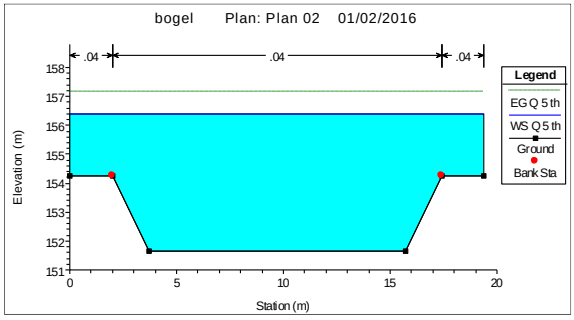

Fig. 6 Water level at cross section point 18.

The second plan is by constructing of small dam to reduce the water level. The function of small dam is to catch the surface runoff before flowing to the channel. In this research, two small dams were applied to reduce the runoff discharge. To find the biggest reservoir volume, the locations were decided on the upstream area. From three alternative location, the location dam 2 and dam 3 were selected to develop the small dams. The three proposed location of dams is shown in Fig. 7. Two selected location of dams are location dam 2 namely Bacem dam and location dam 3 namely Kedung Puring dam. From the analysis results base on the topographic map, for Bacem dam the dam height is 12 m and the reservoir can be intercepted of runoff is 147,064 m^3. For Kedung Puring dam, the dam height is 12 m and the reservoir can be intercepted of runoff is 170,708 m^3. The total volume of runoff can be intercepted by two dams is 317,772 m^3. Comparing with the runoff discharge occurred at outlet of Kali Bogel river (200.31 m^3/sec. and 331.44 m^3/sec. for rainfall with 2 and 5 years return period), the water volume can be intercepted in two dams is very small. The effect of two dams can only decrease the water level 0,5 m. To construct two dams, the budget need is equal to 2.0 million US$. From this analysis it can be concluded that the development of small dam to reduce the water level in Kali Bogel river outlet is ineffective and inefficient.

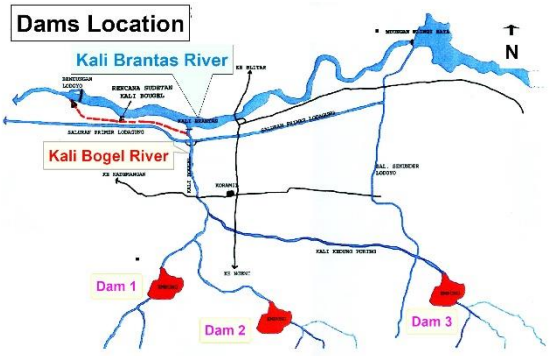

Figure 7. Proposed of dams location.

The third plan was proposed to reduce the flood discharge of Kali Bogel river. The proposed plan is by constructing of floodway. The floodway will differ the Kali Bogel flow direction about 500 m before outlet. The flow direction of floodway is to the new outlet which is located in downstream of Lodoyo dam. The distance from floodway gate to outlet is about 3 km. Because of the floodway outlet is located in downstream of Lodoyo dam, the submerge flow will not occur along the year. The layout of the floodway can be shown in Fig. 8. The trapezoidal cross section type was choose for floodway channel. If the cross section dimension are channel width 10 m, side slope 1:2, channel depth 3 m, channel slope 0.005, and Manning's coefficient 0,025 the floodway way can be carried the discharge equal to 175.91 m^3/sec. The typical of the floodway cross section is shown in Fig. 9. The material of the floodway channel is rubble stone. The discharge flowing through the Kali Bogel river with rainfall intensity equal to the 5 years return period rainfall is equal to 331.44 m^3/sec. If the floodway fully operated, the remained discharge flowing through in Kali Bogel river is equal to 155.53 m^3/sec. With this discharge, the water level in Kali Bogel river will be lower than river bank. Consequently, the flood will not occurred along the river. The discharge which is should be flew to the flood way can be control by the sluice gate on the floodway point. The cost to construct the floodway with 3 km long approximately equal to 1 million US$. This price is chipper than dam construction budged and little bit higher than channeling budged. By considering the construction budged need and decreasing of discharge amount the most effective and efficient of flood counter measure for Kali Bogel river is floodway. Some advantages of the floodway are the submerged flow will not occur at the floodway outlet, the construction budged is reasonable, and the land acquisition can done smoothly. The most difficulties may occurred on floodway construction is land acquisition. This work can done smoothly

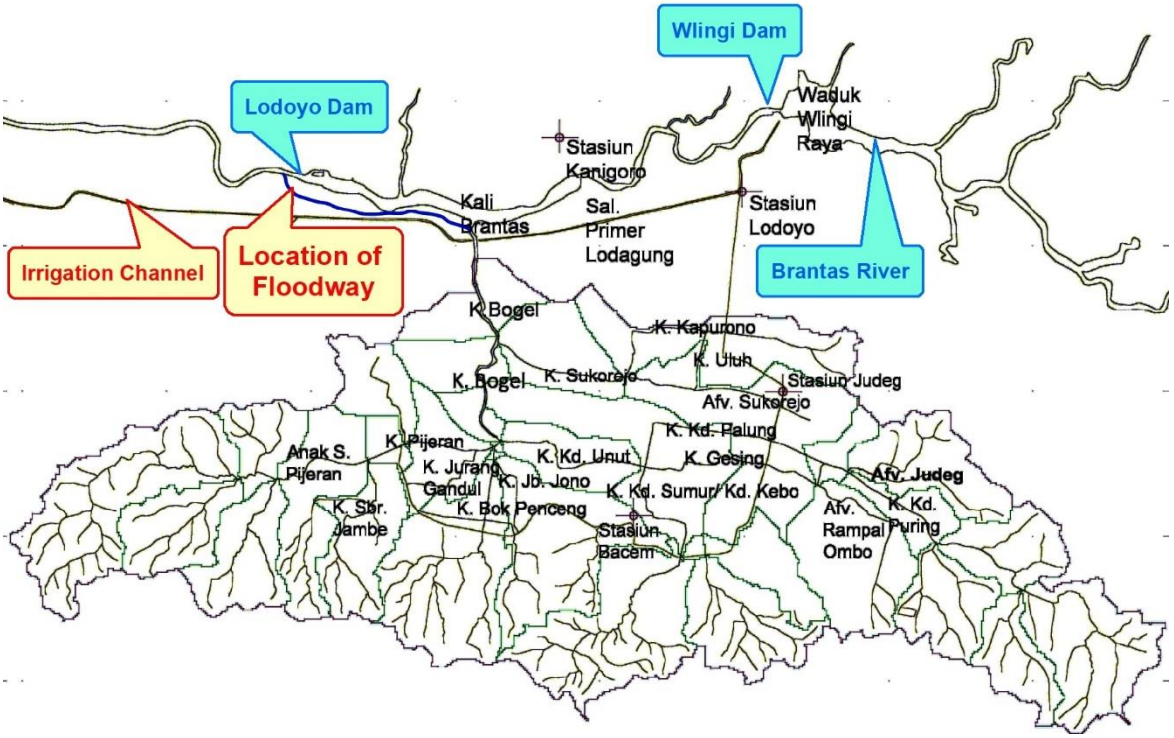

Fig. 8 Layout of floodway

if government can be explained well the purposed of the floodway and the advantaged of floodway. From Fig. 8 it can be seen that the floodway is located between Kali Brantras river and irrigation channel in narrow distance. Normally, land acquisition process for the land located between big river and irrigation channel with narrow distance is easy for government development purpose.

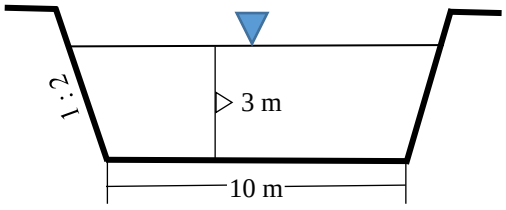

Fig. 9 Typical of floodway cross section

CONCLUSIONS

From this research it can be concluded that the most effective and efficient to reduce the flood occurrences of Kali Bogel watershed is by constructing the floodway. The main reason is the water level at the floodway outlet is higher than Kali Brantas river water level. Therefore, the submerged flow will not occurred. The second reason are the floodway can be reduced the discharge of Kali Bogel river significantly, the construction budged is reasonable, and the project implementation especially for land acquisition look easier than the other method (channelization and dam construction).

ABSTRACT

Mosquitoes have their own preferences in determining hosts to be targeted in finding food. Some of the factors that can attract mosquitoes in finding their host are blood type. This study aims to determine the blood type preference by mosquitoes to landing and characteristics of mosquitoes that like landing and species of mosquitoes that landing on volunteers in Kemelak Bindung Langit Ogan Komering Ulu Regency, South Sumatra. This study uses 12 people who have different blood types. The time of observation of preference landing was carried out for 12 hours from (18.00-06.00) with a time ratio of 40 minutes / hour. with 3 repetitions. Data analysis using quantitative analysis used to determine the blood type needed is by discussing the Method Neu et, al 1974 (Preference Index). The results show that blood type O (1.12), AB (1.08), and B (1.08) are the blood groups that are the preference of mosquitoes to landing compared to blood group A (0.18). The characteristics of mosquitoes in each genus are different, the groups of Anopheles sp mosquitoes have proborcis and palpi characteristics are almost the same length, the Armigeres sp group has a characteristic scutellum consisting of 3 lobes and has a clear wing color. And in the genus Aedes sp has characteristics with the tip of the abdomen that has cerci, and has symmetrical wings and clear colored. The Culex vishnui mosquito species is the dominant mosquito species landing on all blood type systems.

Keywords: Landing preference, Mosquito, ABO blood group, Kemelak bindung langit

INTRODUCTION

Mosquitoes are animals that are ectoparasite which can disrupt the activities and health of humans and animals. This is because mosquitoes generally can be a vector in the spread of disease. In Indonesia there are 457 mosquito species consisting of 18 genera, including 80 Anopheles, 125 Aedes, 82 Culex and 8 Mansonia [26]

Kemelak Bindung Langit is one of the villages located in East Baturaja District, Ogan Komering Ulu Regency, South Sumatra. Kemelak Village is a low-lying area that has several types of habitats such as rice fields, swamps, rivers and plantations. Such environmental conditions are conducive habitats and suitable for breeding mosquitoes. Based on reports from the Ogan Komering Ulu Timur District Health Office it was found there were several diseases caused by Anopheles, Aedes and Culex mosquitoes [12].

Mosquito's preference for sucking blood of different hosts, one of which is a mosquito that likes to suck human blood (anthropophilic). Anthropophilic mosquitoes like to be close to human activities, because it is a very comfortable habitat for breeding these mosquitoes [24].

Female mosquitoes use odor and heat as a reference for locating blood feed so that mosquitoes can detect the blood content of the host over long distances. Mosquito's flight speed will be faster if there is a smell and heat stimulus from the host [39]. Every human being has a different blood group so that the blood and protein constituents of each individual also have different levels. Humans have blood which is included in the ABO blood group system which consists of four main blood groups namely A, B, AB, and O. This causes many people's opinions regarding blood feed preferences based on ABO blood pressure.

Research on mosquito characteristics both morphology, physiology, spread of mosquitoes and mosquito bite patterns on their hosts has been

widely carried out, but research on host characteristics that mosquitoes like has not been done much. Therefore, it is necessary to do further research regarding the host characteristics that mosquitoes like, entitled "Landing Preference for Mosquito Based on Blood Types of ABO System in Humans in the Kemelak Bindung Langit Regency Ogan Komering Ulu Districts".

MATERIALS AND METHODS

Location and Time of Research

The study was conducted from January to March 2019. Located in the Kelurahan Kemelak Bindung Langit of Komering Ulu Regency, and Mosquito Identification in the Entomology Laboratory of the Baturaja Health Research and Development Center.

Materials

There are also tools that are used include, stationery, aspirator, autoclick, blood lancet, petri dish, rubber, alcohol cotton, camphor, digital camera, blood group paper, kuteks, chloroform, hygrometer, insect box, insect pin, sergeant needle , paper labels, microscopes, papper cups, pinning blocks, point pouches, and thermometers. While the material of this study was mosquitoes as the object of research, 12 volunteers with different blood groups and Anti A, Anti B, Anti AB, and Anti D Reagents were used to see the presence of agglutination in the blood group.

Methods

Determination of Blood Type

Clean your fingers with alcohol cotton. Capillary blood taken using autoclik. The first blood is cleaned and the blood is then used for examination. Then place it in the column available on blood type paper. Dropped by each reagent according to the available column. Homogeneous. Judging by agglutination and the results recorded.

Observation of Landing Preferences Mosquito Based on Differences in Blood Types

Preference observations of landing mosquitoes were carried out in the neighborhoods of the Kemelak Village of Komering Ulu District. This study used 12 volunteers consisting of 3 blood groups (A, B, AB, and O). When observing the preferences of landing mosquitoes carried out for 12 hours from (18.00-06.00) with a time ratio of 40 minutes / hour. Mosquitoes that land on their hands and feet are captured using an aspirator and count the amount based on each blood group. This research was conducted with 3 repetitions with the same method and location.

Mosquito identification

Identification of mosquitoes to species level is carried out at the Baturaja Health Center Laboratory. The mosquito samples obtained were identified by observing the characteristics of the mosquitoes using a microscope while to find out the mosquito species name using the O'connor mosquito identification book, C.T. and T. Sopa, 1981 and Rattanarithkul, R., 2010.

Data analysis

Quantitative analysis used to determine the most preferred blood group is the Neu Method approach (Preference Index). According to Neu *et al*. (1974), If $w \geq 1$, the blood group concerned is preferred. The *w* value obtained from the calculation results is a preference index, then the Preferemsi Index value of the type of blood group is divided into two criteria. that is :

a. If $w \geq 1$ = preferred
b. If $w \leq 1$ = not liked

Determination of the Neu Method (Preference Index) according to Neu *et al*. (1974) can be seen in Table 1.

Table 1 The criteria measured in determining the Neu index

Blood Type	availability		Use		Preference Index		
	b	p	n	u	E	w	b
x1	a1	p1	n1	u1	e1	w1	b1
x2	a2	p2	n2	u2	e2	w2	b2
x3	a3	p3	n3	u3	e3	w3	b3
x4	a4	p4	n4	u4	e4	w4	b4
Total	an	pn	nn	un	E n	wn	bn
		1,00		1,00			

Description:
a = number of volunteers in blood group
p = proportion of the number of blood groups
n = number of each type of blood group infested by mosquitoes
u = proportion of each type of blood group that is infested by mosquitoes (ni / ∑n)
e = expectation value
w = preference index (ui / pi)
b = standardized selection index (wi / ∑w)

RESULTS AND DISCUSSION

Based on the research that has been done on the preference of mosquito perch based on ABO system blood type in humans in Kemelak Bindung Langit Village, South Sumatra Komering Ulu Regency, the results showed that the total number of mosquito samples obtained in this study were 361 individuals. The preference of mosquito perch based on ABO system blood type in humans in Kemelak Bindung Langit Village, South Sumatra Komering Ulu Regency can be seen in Table 4.1.

Table 4.1. Index and preference level of mosquito landing prefer based on blood type on volunteers in Kemelak Bindung Langit Village, Komering Ulu Regency, South Sumatra

Blood Type	Volunteer availability	Mosquito Landing Total	Preference Index (w)	Level Preference
A	3	64	0,72	4
B	3	97	1,08	3
AB	3	99	1,08	2
O	3	101	1,12	1

In Table 4.1. shows that blood groups O, AB, and B tend to be preferred by mosquitoes to perch. This is indicated by the index value of the mosquito perch obtained, in blood group O the preference index is 1.12 which tends to be higher than the other blood groups. While blood group AB and B get a preference index value of 1.08 and for blood group A get a preference index value of 0.72. Blood type A is included in the category of dislikes for mosquitoes to perch because of the preference index of blood type A> of 1.

Based on the results, it was found that the tendency of mosquitoes to perch on blood type O was in line with the research conducted by Shirai et al., (2004) (83.3%) compared to other blood groups.

The blood provides high iron levels as hemoglobin in erythrocytes and as transferrin iron. Iron plays an important role in living cells as a cofactor of proteins involved in various metabolic pathways such as DNA synthesis and repair, energy metabolism and immunity, and in mosquitoes, iron and proteins found in blood play an important role in the production and development of mosquito eggs. The tendency of mosquitoes to perch on blood type O is thought to be due to differences in levels of protein and iron contained in human blood. According to the results of Geiseret al., (2006), one of the proteins associated with iron in mosquito metabolism is ferritin. Besides ferritin protein according to transferrin also plays a role in mosquito metabolism[17].

Transferin iron and heme iron (ferrritin) found in human blood play a role in metabolism and the development of mosquito life cycles. That ingested iron from the blood which has been eaten by the Aedes aegypty mosquito in the form of 3.6 ng Transferin-Fe by (77%) is used for the development process maturation of mosquito eggs, (15%) is used for the body's metabolic processes and (8%) is excreted as waste from waste metabolism. Whereas from 1881.1 ng Heme-Fe absorbed by mosquitoes by (6%) was used for body metabolism, (7%) was used for egg maturation and (87%) was excreted as waste from waste products from metabolism [44]. However iron derived from heme and transferrin is distributed differently at the end of the gonotropic cycle. The majority of iron stored by the Aedes aegypty mosquito at the end of the first gonotropic cycle comes from heme because of the much greater heme level in the blood.

Regarding the level of ferritin and serum iron in the ABO blood group system in Enugu Southeast Nigeria the results showed that blood group O had a ferritin value of (116.75 ± 46.34) (ng / mL) and serum iron of (24.00 ± 6.75) (ng / mL) while blood group B has lower ferritin and iron iron values which are equal to (83.58 ± 57.7)

(ng / mL) and (20.20 ± 8.07) (ng / mL) compared to other blood groups [27]. However, for transferrin levels there was no significant difference in all blood groups. It is suspected that there are differences in levels of iron and proteins that distinguish the preference of mosquito perch on the ABO system blood group.

Characteristics of mosquitoes landing the results of identification of mosquitoes that landed on volunteers were found as many as 5 genera of mosquitoes consisting of 17 species. The mosquito species obtained can be seen based on the table as follows :

4.2. Table of Species of Mosquitoes that Perch on Volunteers Based on the Four Blood Types of the ABO System

No	Genus	Spesies	Golongan Darah			
			A	B	AB	O
1.	*Aedes*	*Aedes albopictus*	-	1	-	-
		Aedes albolineatus	-	-	1	-
		Aedes lineatopenne	-	1	1	1
		Aedes vexans	1	1	-	-
2.	*Anopheles*	*Anopheles barbumbrosus*	-	1	-	-
		Anopheles barbirostris	-	2	-	-
		Anopheles flavirostris	1	-	-	-
		Anopheles sinensis	1	-	-	-
		Anopheles vagus	25	32	31	23
3.	*Armigeres*	*Armigeres subalbatus*	-	2	6	4
4.	*Culex*	*Culex bitaeniorhyncus*	1	-	-	-
		Culex gellidus	-	2	-	1
		Culex tritaeniorhyncus	4	2	2	5
		Culex quinquefasciatus	4	7	8	10
		Culex vishnui	25	44	45	49
5.	*Mansonia*	*Mansonia annulifera*	2	4	4	2
		Mansonia uniformis	-	-	1	-

The mosquito species obtained in this study are variously seen because the mosquito samples obtained represent the five genera of mosquitoes in Indonesia, namely from the genus Anopheles, Aedes, Mansonia, Armigeres, and Culex. This is also influenced by ecological factors

The study area in Kemelak Village, Bindung Langit, is a low-lying area that has several types of habitats such as rice fields and plantation land. In addition, at the research location there are also cattle sheds. So that with a diverse habitat for living habitat, this is what supports it as a habitat for various species of mosquitoes [12].

In table 4.2. It can be seen that the mosquito species that dominates more on the blood group are the Culex vishnui mosquito species 49 perched on the blood group O while the mosquito species which are the least perched are Aedes albopictus, Aedes albolineatus, Aedes lineatopenne, Aedes vexans, Anopheles barbumbrosus, Anopheles flavirostris, Anopheles sinensis, Culex bitaeniorhyncus and Mansonia uniformis.

Culex vishnui has a habit of biting humans and animals at night. The time usually used by Culex

mosquitoes to suck blood is a few hours before the sun rises and after the sun sets [40] This caused the Culex vishnui to dominate the study because the study was conducted at 6:00 a.m. to 6:00 a.m. which was the time when the Culex mosquitoes were active in their activities.

The place that is usually used by Culex sp mosquitoes to breed is dark, protected from sunlight, the surface is wide open, contains clear water, and calm [37]. In the study site, there were several open sewers, puddles of water and swamps and trees. Which stated that Culex mosquitoes usually chose puddles of groundwater as their breeding places, such as in hollow trees. bamboo stems and stumps, and other water reservoirs [33]

Based on table 4.3 mosquitoes have different characteristics. Anopheles sp mosquitoes have the main characteristics that distinguish anopheles sp mosquitoes from other mosquito groups which have proborcis not bent down with proborcis and palpi sizes almost in the long term whereas for the other genera it has probiotic size and palpi not equal length [26]. While the Armigeres mosquito has characteristics with a larger body size compared to Aopheles sp, Culex sp, Aedes sp, and Mansonia sp mosquitoes and has a rather curved probosis [30]. for groups of genus Culex sp and Mansonia sp have scutellum which consists of 3 lobes and has a clear wing color. As well as in the genus Aedes sp has characteristics with the end of the abdomen that has cerci, and has wings that have symmetrical wings and are generally clear in color [26].

4. CONCLUSION

Based on the research that has been done, it can be concluded as follows:

1. Blood type O (1.12), AB (1.08), and B (1.08) are blood groups that are the preference of mosquitoes to perch compared to blood group A (0.18)
2. Characteristics of mosquitoes in each genus are different, groups of Anopheles sp mosquitoes have proborcis and palpi characteristics are almost the same length, the Armigeres sp mosquito group has characteristics with a larger body size compared to other mosquito groups whereas with other mosquito groups while for the genus Cules sp and Mansonia sp it has the characteristics of scutellum consisting of 3 lobes and has a clear wing color. As well as in the genus Aedes sp has characteristics with the end of the abdomen that has cerci and has symmetrical and clear wings
3. The Culex vishnui mosquito species is the dominant mosquito species prevailing in all blood type systems.

ORGANIC CYCLE SYSTEM IN BIOGAS SYSTEM: THE RECYCLING OF BIOGAS SLUDGE FROM COW MANURE AS BIOCHAR FOR BIOGAS PURIFICATION

Ambar Pertiwiningrum[1,3,5], Andang Widi Harto[2], Margaretha Arnita Wuri[3,4], Adam Gemilang[2], Rachmawan Budiarto[2,3,4] and Misri Gozan[3,4]

ABSTRACT

The increase in intensive using of production elements has been reflected on the increasing amount of organic waste. Without appropriate treatment, waste leads to the contamination of environment. The conversion of organic waste into material with economic value will contribute to increasing productivity, for example in biogas system. Today, the utilization of waste from biogas processing (biogas sludge) as bio-fertilizer has been developed. However, the utilization of biogas sludge from cow manure as biochar is still rare. The aims of this study were to investigate the recycling of biogas sludge from cow manure as biochar in biogas purification. Biochar made of biogas sludge from cow manure as adsorbent in biogas purification leads to the cycle loop of biogas system. We also investigated the effect of mass variation of biochar made of biogas sludge from cow manure on biogas purification performance. The variation of zeolite and biochar made of biogas sludge with mass ratio of 0:80; 20:60; 40:40; 60:20; and 80:0 per each column had been put inthe adsorption column of biogas purification. The results showed that the increase in biochar mass affected on methane enrichment of biogas. The highest methane enrichment (22.57%) was performed by biogas purification using biochar with ratio 40:40. The utilization of biochar mass above 50% of the total mass per each column decreased methane enrichment. From this study, we concluded that biogas sludge has potential to be used as adsorbent in biogas purification. The recycling of biogas sludge into biochar leads to organic cycle system in biogas system that provides option in sustainable energy and additional benefits for farmers.

Keywords:Organic cycle system, Biogas sludge, Biogas purification, Biochar

INTRODUCTION

Livestock contribution to environmental problems is on a massive scale. Along with economic growth, food demand including meat and milk will increase day by day. The global production of meat is projected to be more than 460 million tonnes in 20150 [1]. The impact on environment may be direct, through grazing and organic waste, or indirect, such as the expansion of land for feeding. The organic waste from livestock comes from their manure. Livestock manure is primarily composed of organic material and water, and it is accumulated annually without treatment. If the waste get into the water or accumulate, it can contaminate freshwater and soil. Moreover, in aerobic condition, the organic material is decomposed, producing methane and carbon dioxide gases.

The population of livestock in Indonesia increases annually and unfortunately is not accompanied by a good waste management. Most of the livestock farmer groups in Indonesia still maintain conventional management without waste treatment. The organic cycle system is expected to be an alternative solution in livestock waste management. The cycle of organic material is managed through 9R (reuse, reduce, recycle, refill, replace, repair, replant, rebuild, and reward) [2]. It means livestock manure can be recycled into renewable resources to high value product like biogas. Biogas technology allows us to use methane generated in anaerobic condition for cooking or lighting. The organic cycle system can provide sustainable economic, social, and environmental aspects out of organic waste. Moreover, if organic cycle system is developed with circular economy system model, it will give a good local economic. The development of circular economy does not only utilize organic waste but also practice a profitable business from organic waste [3]. The circular economy in livestock sector means maximizing natural resource yields by circulating the production

[4] for example by turning livestock waste into energy. Today, the development of circular economy model in livestock sector does not only change waste into energy but also waste into material.

In biogas production, the waste will produce solid by-product like biogas sludge. Many reported the use of biogas sludge for fertilizing [5]-[6]. The studies about the use of biogas sludge as biochar are still rarealthough biochar has the economic added value. Biochar is a solid material obtained from thermochemical conversion of biomass in limitless oxygen condition [7]. Biochar is commonly used as soil enrichment. In this study, we tried to investigate biogas sludge utilization as biochar for biogas purification.

METHODOLOGY

Materials

Biogas sludge from cow manure is used for raw material in biochar production. Before the biochar production process beginned, biogas sludge was dried under the sunlight for 24 hours. Then dried biogas sludge was pyrolyzed at 225^{o}C for four hours in pyrolysis reactor. The pyrolysis of biogas sludge generated biochar that can be used for biogas purification.

Biogas Purification

Biogas purification is a method to clean biogas content from impurities such as carbon dioxide, hydrogen sulfide, volatile organic compound, et cetera [8]. In this study, we investigated the utilization of biogas sludge-basedbiochar to capture carbon dioxide in biogas. Carbon dioxide capturing on the surface of biochar was expected to increase methane composition and calorific value.

The increasing number of biogas plants will also increase adsorbent demand. To fulfill the demand, biochar production from biogas sludge will be an alternative solution.

Biogas purification was carried out by the adsorption method with two integrated adsorption columns. The length and diameter of the column was 200 mm and 40 mm respectively (Fig. 1). The design of the column was adopted from Lalhmingsanga [9] with modification.

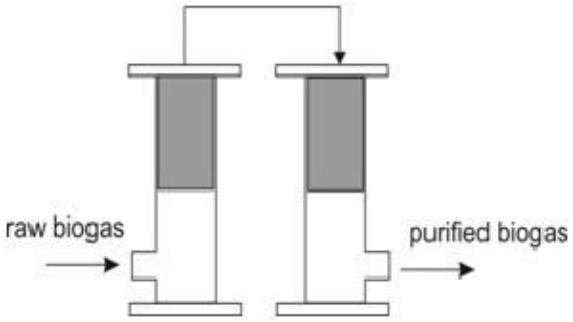

Fig. 1. Design of adsorption column [10]

Each column contained 80 grams of adsorption. The composition formulation of adsorbents is shown in Table 1.

Table 1. Formulation of adsorbents in biogas purification

Samples	zeolite (grams)	biochar (grams)
AS 1	80	0
AS 2	60	20
AS 3	40	40
AS 4	20	60
AS 5	0	80

The adsorption process was carried out at gas pressure ranged between 5-7 bar for 10 minutes. The methane compositions in biogas were analyzed by gas chromatography (GC).

RESULTS AND DISCUSSION

Biogas Purification

Biogas purification aims to minimize impurities in biogas such as carbon dioxide and increase its methane composition. Before and after the adsorption, the composition of biogas was analyzed using gas chromatography (GC). In this study, the capability of biochar to capture carbon dioxide (CO_2) was shown by the increase in methane (CH_4) composition. The biogas compositions before and after the adsorption are presented in Table 2.

Table 2. Methane compositions in biogas before and after adsorption

Samples	CH_4 before adsorption (ppm)	CH_4 after adsorption (ppm)	The increase in CH_4 (%)
AS 1	139448.78	140112.10	0.48
AS 2	138768.05	148754.20	7.20

AS 3	103153.36	126439.67	22.57
AS 4	113874.55	120584.95	5.89
AS 5	148599.30	143036.02	-3.74

Table 2 shows that after the adsorption using biogas sludge-based biochar, the methane in biogas increased. It means the biochar was capable to capture carbon dioxide. The performance of livestock waste-based biochar in capturing carbon dioxide is also reported by Minh-Viet and Byeong [11]. The combination of zeolite and biochar that could increase methane were AS 1, AS 2, AS 3, and AS 4. Carbon dioxide adsorption capacity at different mass of biochar resulted in different methane enrichment. The increase in methane performed by AS 1 was the lowest increase (0.48%). The higher increase in methane was performed by AS 2 (7.20%). By adding biochar composition in the combination of adsorbent, methane content increased. The highest methane enrichment was performed by AS 3 with the composition of 40 grams of zeolite and 40 grams of biochar.

Biochar is a solid material formed by thermochemical decomposition of biomass.The main element of biochar is carbon (C). Because of the carbonization process, biochar has a porous structure that can be used to capture carbon dioxide [12]. The surface pores of biochar havea key role in capturing carbon dioxide so the increase of biochar mass will increase the surface pores of biochar [13]. However, the increase in methane was lower compared to AS 3 when biochar was added to be 60 grams. Even the use of 80 grams of biochar actually decreased the methane composition of biogas from 148599.30 ppm to 143036.02 ppm. In other words, there was a decrease of -3.74% in methane concentration.

Previous study reported that biochar captures carbon dioxide more than methane [14]. It means biochar can adsorb methane, but not as much as adsorbing carbon dioxide. In fact, the use of 80 grams of biochar under these conditions caused the reduction of methane. It was possible that carbon dioxide had been maximally adsorbed and in these conditions, methane was also adsorbed.

The optimum combination of adsorbent in this study was performed by AS 3 with the formulation of 40 grams zeolite and 40 grams of biochar (see Fig. 2).

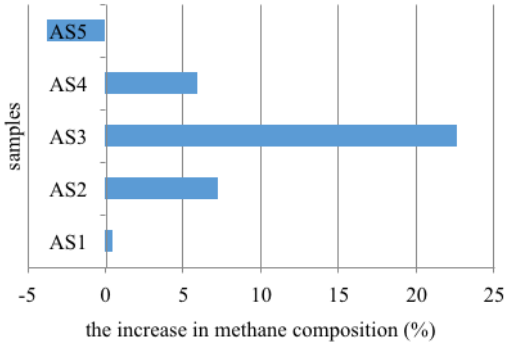

Fig. 2 The increase in methane composition after adsorption using AS 1, As 2, AS 3, AS 4, and AS 5

Recommendation of Organic Cycle System in Biogas Technology

Based on this study, biochar from biogas sludge has the potential to be developed to advance carbon dioxide capturing in biogas purification. Although this investigation is an initial study but the use of biogas sludge as biochar for biogas purification will lead to organic cycle system and circular economy.

Therefore, in this study we recommended a new concept in biogas system that is integrated with biogas purification using biogas sludge. Biogas sludge was recycled to be adsorbent in biogas purification. This concept aims to develop a model that has no effect on environment and ensure that there is no reduction in waste production [15]. It also becomes a solution in managing livestock waste, upgrading the quality of biogas, and increasing self-sufficiency energy. Moreover, biochar that have been used for purification can be used as soil enrichment. In this concept, no waste is wasted.

Biochar utilization that is integrated with biogas system is appealing because it is a safer method of organic waste management. The concept of organic cycle system in biogas system is shown in Fig. 3.

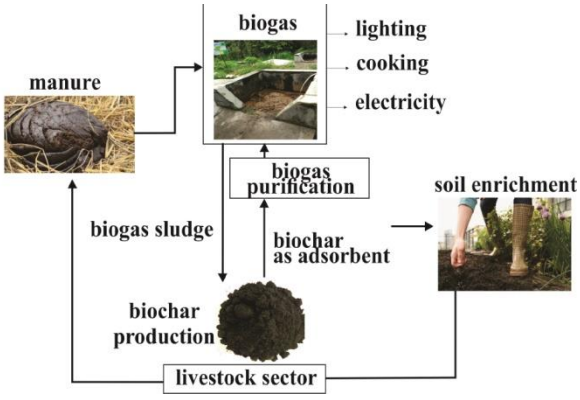

Fig. 3. Concept of organic cycle system in biogas

system

CONCLUSIONS

From this study we concluded that the optimum mass of biochar in the combination of adsorbent for biogas purification was 40 grams. The combination of zeolite and biochar with the composition of 40:40 can increase 22.57% of methane composition in biogas compared to biogas before purification. In this study, the utilization of biochar from biogas sludge is more appealing in biogas system. Besides being able to increase methane composition in biogas purification, the concept of organic cycle system in biogas system leads to zero waste management.

ACKNOWLEDGMENTS

The research was supported by Grant Program from Gadjah Mada University, Indonesia through PTUPT program. We gratefully acknowledge the support from USAID through the SHERA program – Centre for Development of Sustainable Region (CDSR). In year 2017-2021, CDSR is led by Center for Energy Studies - UGM. The authors also would like to thank the students of Faculty of Animal Science for the contribution in collecting the data.

SEMANTIC OUTLINES OF MODERN GEOGRAPHY

Viacheslav D. Sukhorukov, Yuriy N. Gladkiy
Herzen University, 48, Moika Emb., St. Petersburg, Russia, 191186
E-mail: suhor@herzen.spb.ru; gladky43@rambler.ru

ABSTRACT

The authors consider the process of geographical knowledge of spatial reality, perceived as a multi-level structure. The image of geographical science is presented in new contour lines and research opportunities. There is hardly sufficient reason for geographers to "privatize" space – one of the three categories of the world (space, time and matter), since all Sciences have spatial quality. Geography is not a "super science" of spatial relations, since this assumption automatically narrows the field of study of many other Sciences, as well as can not be considered a generalizing or law-making science of spatial relations. It is argued that by its very nature topology does not and cannot answer the basic question of geography about the identification of the subject of science. The authors' position is reduced to rethinking the structural content of modern geography and actualization of its subject image. This does not change the main object of geography - connections, interactions, circuits, correlation relations, etc., confined to a specific spatial arena and beyond the microcosm. The role of praxiology - the doctrine of human activity, the realization of human values in real life-is increasing.

Key words: geographic factology, geographical phenomenology, geographic modeling, geographical conceptology, geographical praxeology, popularization of geographical knowledge.

INTRODUCTION

The public and disciplinary status of any area of knowledge depends on condition of a subject, semantic depths, presence (or absence) paradigm effect, a method, a point of view (and, certainly, degrees of error of the scientist). A number of knowledge, including geographical, is distinguished by its multifunctionality, being simultaneously a *science* and *not a science*. Some geographers operate with measures of scientists, others with measures of travelers or specialists in art. It is remarkable the lot of philosophy in which frameworks (natural philosophy) the first geographical views have been arisen. Today it doesn't serve neither to the science s nor theology though we can duffer in it the scientific and religious philosophy together with existentialism, postmodernism etc. Therefore the statement about existence of different kinds of philosophical knowledge is fair. Acting as a reflection over the world outlook universalism, basic values of culture, the philosophy has as though passed in the development two stages: the first associates with transformation universalism of cultures in philosophical categories (here vainly to search for visible scientific achievements); the second - it is connected with judgment primary category samples turning to strict definitions with which philosophers operate as theoretical ideal constructions. In this being the philosophy appears as enough strict theoretical science in spite of the fact that it contains obviously unscientific components in other quality.

It is known the part of knowledge exists at a joint of social, natural and existential, in "a backlash" (in "a condensation kernel") between objective and subjective, natural-scientific and humanitarian. (Hence, the "vicious" division of sciences into natural and humanitarian, their vision in a "black-and-white" range). This knowledge in many respects associates with *geography in general and in particular with human geography*.

Geography deals with the study of the earth's space. It is believed that the earthly reality for the past time thoroughly studied geography, so now it remains only information and didactic functions. However, the world is conceived by an extended eternity, rejected from direct vision. Therefore, the power of geography is now moving into the semantic area, which is proportional to the experiences and feelings of life. This orientation of comprehension of space clearly distinguishes modern geography among other areas of knowledge.

PURPOSE AND METHOD OF STUDY

Now modern geographical science understands the subject of all that is required in the act of judgment, representation and sense of spatial reality through the stages of self-consciousness, culture, morality, art, religion, philosophy. The embodiment of the world now takes place in a plentiful and polysemous association of images, closely related to the semantic experience of understanding space. That is, the scope of the current geography includes not only the universality of natural nature, built on the principle of determinism, but summarizes the

total existence, located outside the predicates of physical phenomena.

The aim of this study is to highlight the main cognitive projections of the new geography. In this case, the leading method the authors recognize *the idiographic analysis* of structural and cognitive levels of geographical science in the context of a holistic perception of theory and practice. At the same time, *the homothetic approach* advocated by many theorists of geography (the essence of which is to establish laws, to quantify geography, to mathematize it, to develop isomorphic models of spatial structures, etc.), is considered by the authors to be at best auxiliary in relation to the homothetic.

RESEARCH RESULT

Geographical Factology

Geographical knowledge contains a huge amount of empirical and factual information and materials. The study of facts and methods of their knowledge as a result provides scientific comprehension of geographical reality. Thus, geographical factology is the area of scientific knowledge about the methods of description and analysis of geographical objects, phenomena and processes in order to systematize them.

Geographical fact is a phenomenon, event or process realized by the researcher, the reliability of which corresponds to objective reality and is established empirically. Many questions arise here. For example, should geography study the whole complex system of supra-biological programs of human activity or only its separate fragments? Is it not more logical to put the external, materialized, objectified part of history related to the real geospheres into the subject field of cultural geography research, and to leave the culture that is fixed in the mentality, morals, customs, in the living experience of people's life together, mainly to the representatives of related sciences? Where are the boundaries separating cultural geography from economic and social geography, sociology, philosophy of culture, cultural anthropology, cultural studies, cognitive psychology?

Phenomenological approach in geography (rooted in the works of *Carl Sauer*), can be perceived as a valuable scientific reflection only when it comes to the study of perception and subconscious structuring of the natural environment and geospatial, the assessment of the quality of the natural environment (with access to the project and district planning), and even when subjected to the analysis of works of art, to illuminate the pages of paleography (how the landscape of a country). In those cases, when instead of facts it is proposed to study the perception of phenomena and to distinguish the relationship between them by means of visual, auditory or taste sensations, we can not talk about valuable scientific rationality. Recall: in phenomenology, a special place is given to imagination, fantasy (for *Edmund Husserl* - German philosopher, founder of phenomenology fantasy is more important than perception!), giving the possibility of free, unlimited variation of examples necessary for the comprehension of the essence.

Thus, the concept of fact in geographical knowledge remains one of the most difficult, since spatial givens are based on the multiple nature of what is happening. Therefore, the boundaries of geographical fact are usually fixed by its meaning and logical position of the researcher.

It should be emphasized that in spatial reality the fact can not only appear, exist, but also disappear. This suggests that the fact of science must be present in a holistic system of geographical knowledge, in the operational, semantic and conceptual sections of the entire subject area of geography. In these meanings, geographical fact embodies the semantic structure and information potential of space.

The formation of geographical fact is carried out by means of factual search in the logic of understanding and explanation of the object under study. This means that the actual data in geography are of particular value for science and practice. In this case, the description of the facts without their analysis and generalization (*factography*) is usually used to characterize the experience or for other purposes. Systematized facts that reflect the essence of the studied object, the connection between phenomena and events (*factology*), reveal features of the organization of individual components into the whole process. Thus, factography and factology to create the *texture* of the geographical space. On its basis the General statements having explanatory power are formulated [4].

Geographical facts have multiple parameters and characteristics by which the regularities of spatial reality are fixed. Interpretation of geographical facts can be carried out in various ways and techniques. The intensive development of geographical factology in recent decades has led to the formation of a special science - *geoinformatics*, which is engaged in the collection, processing and presentation of information about the properties of objects, processes and phenomena occurring on Earth. Geographic information systems (GIS) databases are used to gain new knowledge and to solve practical problems. Figuratively speaking, GIS technologies in geography are simultaneously “a telescope, a microscope and a computer” [3].

Geographical Phenomenology

Phenomenology is a field of research that contains the roots of various sciences and concentrates the researcher’s attention on the

problem of perception of space and space. The leading approach of phenomenology is the description of "animate natural reality." At the same time, phenomenology reveals the "sources" from which the basic concepts and ideal laws of pure logic "flow". In turn, the latter should provide the required understanding of the subject, “clarity and distinctness” of concepts and laws, which give objective knowledge and theoretical unity to all knowledge. Consequently, phenomenology means the seizure of objects, “that everything subject to analysis should be worked through in direct demonstration and direct proof” [6], [7].

If a phenomenon is considered only what constitutes being, then phenomenology in turn implies a descriptive philosophical method capable of providing science with reliable cognitive tools. At the same time, phenomenology is not limited to the “real” orientation. Above the reality is the opportunity. Therefore, phenomenology embraces realities and opportunities, the present and the future. Thus, geographical phenomenology is a conscious experience of the embodiment of spatial reality and possibility, represented by unique essential attributes. In the study of phenomenal images of space, the phenomenological methodology of knowledge should be decisive as a dialectical translational movement from sensual immediacy through the stages of science to “absolute knowledge” [5]. The thinking of such a plan is capable of producing a kind of phenomenological reduction, meaning the reduction of being to phenomena and putting the world beyond the brackets. The most important feature of this consciousness is its intensity, that is, the focus on any object. The “entities” generated in this way have the meaning of “individual data” belonging to the corresponding “essence”. In other words, the universality of entities and constituent of the ultimate task of geographical phenomenology. Consequently, the phenomenological consciousness is the reliance of the world, that is, a direct focus on this, on the subject of "intensionality". As a result of the “Intentional Experience”, the world becomes a “world phenomenon”. In this sense, phenomenological attitudes make it possible to construct such structures of being that are of ideal subjectness for a particular person. These actions are carried out in the experiences of consciousness that give rise to the value meaning of geographic space in its “intensionality” images [7].

With the help of phenomenological consciousness, all kinds of theoretical dualisms are overcome. At the same time, the human world, in essence, turns into “for-itself-being”. Hence, a person strives to become being itself, and any human desire is only a lack of being [5].

This imperative sets a perfectly defined ontology, in which the external world is viewed as permeable to a person and possessing the necessary semantic density. This world has its own tension, able to bring outrage in the field of human consciousness and action. Such a world becomes transparent to the thinking individual. This semantic substantiality means that in every decision a person chooses the whole world.

Geographic Modeling

Modeling as a method of knowledge acts as an intermediate link connecting the object of study with the subject. At the same time, modeling is an integral part of a scientific concept, a kind of skeleton of theory. Much has already been said about the role of modeling and the significance of models in geography. In general, it can be argued that geographical modeling is the process of constructing and researching a standard image of a spatial object, on which scientific theory and practice are oriented.

The whole process of geographical modeling is based on the structural limitation of the qualitative content of the object to be cognized. The result is a strictly defined structure that covers only the elements and relationships of a certain composition and character. It follows that for large geographic complexes the stock of models is practically unlimited.

The final stage of the simulation is a mental or material realizable construction reflecting the object of study. The model allows you to formalize the analyzed problem and integrate a way of understanding and explaining the essence of a geographical phenomenon or process. At the same time, the model performs the function of scientific foresight, has a heuristic value, and provides for obtaining new object data hidden from empirical measurements.

The main tool of geographic modeling and search criteria for the optimization of spatial structures are now GIS technologies. With their help, it is possible to ensure the proportionality of the main ingredients of the geographical space. Efforts in this direction are focused on creating a universal model of the world.

Summarizing the accumulated experience, we can distinguish functional and dynamic models of geographic space. The first fixes the relationship of components within the space. The latter are designed to identify and analyze various state variables of the analyzed geographical objects.

Information models of natural complexes and world systems, which have received many interpretations, are particularly well known in geography. In the meantime, the causal matrix underlying the actual picture of geographic space is extremely complex. The tangle of systemic interdependence in the real world, in the words of

the American geographer W. Isard, is "truly monstrous." However, taking into account the concept of geographic space, its universal dominant is the space of human society. It localizes the socio-economic practice of people, which is a sphere of interaction between society and the natural environment.

Geographical Conceptology

A concept is a semantic unit of representation of one or another form of scientific judgment. This may be related to a concept, idea, theory, or training. They, in turn, determine the boundaries and scope of scientific knowledge development and the possibility of its transformation into reality [1].

Thus, the geographical conceptology is a system of views and considerations that reflect the scientific point of view in the form of ideas and constructive principles in explaining and changing the subject of the study.

The main attributes of geographical conceptology are social conditionality and the scientific and practical need for new ideas, but also the depth of the subject coverage and targeting of recommendations. The degree and level of conceptuality may vary. Therefore, there are many variants of geographical concepts - from scientific justifications and declarations to applied design and experimental actions.

The theoretical constructs of the classics of geographical science and authoritative modern scientists (including representatives of the regional economy) - *W. Christaller, N. Kolossovskii, T. Hagerstrand, F. Perroux, Yi-Fu Tuan, D. Harvey, E. Soja, D. Massey, B. Rodoman, M. Porter, P. Krugman,* etc, are outstanding examples of geographical conceptology. Despite the high level of abstraction of many geographical concepts, they tend to be problem-oriented. This is confirmed by the theories of geographical determinism, numerous concepts of regional development, etc. In the content of geographical conceptology, the most important fact is the process of transition from the essence of the interpreted object to the normative part. It provides a general idea of what should be considered an ideal and how this can be approached. Finally, the agreed standards are transformed into projects that acquire the language of practical action.

The set of geographical ideas, reflecting the measure of knowledge and scientific understanding of the studied spatial reality, creates a kind of conceptual field of geography. His condition is directly related to the structure and directions of development of geographical science. The current stage of the formation of the conceptual field of geography can be named by paradigmatic. Therefore, modern geographical studies use systems of developing concepts and explanatory procedures that correspond to the genesis and logic of science in understanding and constructing an ideal plan of action.

Geographical Praxeology

Praxiology is the doctrine of human activity, the realization of human values in real life. As a research area, it covers the sphere of socio-economic practice of society. the most developed section of praxiology now is sociological and economic theory. Geographical praxiology identifies special structural range of scientific disciplines, making effective substantive reflection of the achieved level of knowledge. thus, the essence of geographical praxiology is the research specifics and practical recommendations for the arrangement of geographical space. One of the clearest examples of geographical praxiology is *currently geopolitics*. now this term has a very wide circulation. Its frequent use directly or indirectly indicates the demand for geopolitical thought, the conceptual topic of which has a synthetic character. In this sense, geopolitics is a holistic methodology that explains the "attitude of the state and society to space" [2].

At least "praxeological" is also *geoeconomics*. It is a complex transregional economic space that includes economic, ethno-cultural and social structures aimed at long-term planning for large-scale redistribution of resources, financial flows and world income as the main source of systemic profit. There is an opinion, geoeconomics is a "global economic federation, a kind of way of intensive economic development of the material world" [10].

Special praxeological role of *geoecology*. It is based on the idea of reasonable interaction of geographical space and human society. This is a kind of reaction of public consciousness, which came to understand the place of man in nature. The core of modern geo-ecology is the phenomenon of the value of the world and the self-value of life in general. To date, this idea of geoecology has become widespread and of global importance [8], [11]. Of course, the mentioned areas of "modernistic" scientific knowledge do not reduce the enormous role of traditional scientific disciplines: physical geography, economic, social, etc.

Popularization of geographical knowledge

The main organizational form uniting geographers of the whole world is the international geographical union (IGU), established in 1922. The international geographical union has the following main goals:

1. To promote the study of geographic problems;
2. Initiate and coordinate geographic research requiring international cooperation, ensure their

broad scientific discussion and publication of results;

3. To ensure the participation of geographers in the work of international organizations;

4. Assist in improving the collection and dissemination of geographic data and documentation;

5. To facilitate the holding of International Geographical Congresses, regional conferences and specialized symposia, the themes of which correspond to the goals of the Union.

6. Participate in any other forms of international cooperation to promote geographical research and the application of their results in practice;

7. To promote international standardization and unification of methods, nomenclature and symbols used in geography.

Geographical societies also play a huge role in the popularization of geographical knowledge. One of the oldest and most honored is the Russian Geographical Society (RGS), founded in 1845. Its founders, among whom were well-known naturalists, travelers and seafarers, identified the cultivation of Russia's geography as the main task of the Russian Geographical Society.

Today, the Russian Geographical Society is an all-Russian public organization that unites almost 30 thousand members in all constituent entities of the Russian Federation and abroad and has regional and local branches, as well as branches and representative offices throughout Russia. One of the priority tasks of the RGS now is the dissemination of geographical knowledge, propaganda of the achievements of domestic and world geography, education of geographical culture, assistance in improving the quality of geographical education among various age and professional groups of the population, teaching geography in secondary and higher education.

Currently, in Russia, in order to popularize geography and increase the prestige of the geographer's profession, a professional holiday is being set - Geographer's Day, which will be celebrated on August 18, the day the Russian Geographical Society was founded.

In Russia, the question is being considered of entering the All-Russian Classifier of the Geographers Study Group, the types of economic activities "Conducting Geographic Research" and the professional standard "Geographer". The establishment of centers for studying geography for schoolchildren at educational institutions of higher education, including within the framework of the national project "Education", is envisaged. The agenda also includes proposals for the implementation of measures aimed at improving the quality of teaching the subject "Geography" in general education organizations, taking into account the priorities and objectives of the scientific, technological and spatial development of the Russian Federation, as well as taking into account the results of monitoring and other forms of objective knowledge assessment students in the field of geography [12].

CONCLUSION

The above considerations lead to the following main generalizations:

- geographical science is constantly being improved, introduces new layers of knowledge into the sphere of its cognitive interest, which requires clarification of its semantic contours;
- modern geography is experiencing a pronounced humanitarian stage of its development, demonstrating a fundamental appeal to the human consciousness;
- in the development of geographical science significantly increases the role of praxiology - the doctrine of human activity, the implementation of human values in real life;
- geographical knowledge is currently embodying the integral representations of the "life world" [9], [13]. These areas of geographical thought also should be reflected in educational geography.

ALTERNATIVE OPTIONS FOR ROAD MAINTENANCE MANAGEMENT IN BANGLADESH UNDER CLIMATE CHANGE CONDITION

M. R. Islam, S. M. Muniruzzaman, Md. K. A. Masud, S. S. Morshed
Department of Civil Engineering, Military Institute of Science and Technology, Bangladesh

ABSTRACT

Bangladesh is one of the worst climate vulnerable countries in the world. It is predicted that temperature and precipitation of the country will increase 1-3% and 20% respectively by 2050. Bangladesh being a flood prone country, roads in the low lying areas will likely to be flooded more frequently than before due to increased rainfall. The study has developed a methodology by Mechanistic-Empirical (M-E) method to find out the effect of moisture on the pavement. It has also provided solutions to minimize the additional damage due to traffic movement on the affected pavement. It is found that damage by a standard axle load during saturation period of 30 days is almost 3 times than that in dry condition. However, during 30 days of saturation if the axle is overloaded by 6 ton, damage is 20 times than that of a standard axle at dry condition. By M-E method it is found that imposing 30 % restriction on standard axle load during pavement saturation condition will minimize the additional damage. The outcome of the study will help road engineers of Bangladesh to combat with the climate change effect by adopting axle load restriction.

Keywords: Climate change, Mechanistic-Empirical method, Pavement saturation, Axle load restriction

INTRODUCTION

The climate change adaptation becomes more critical development issues for Bangladesh. According to scientists, it is predicted that temperature will increase 1-3% and precipitation 20% by 2050 in Bangladesh [1]. Moreover Bangladesh is a flood prone country. Flood water causes enormous damage to the road infrastructure of the country.

Although the road agency of Bangladesh requires 4-days soaked CBR value for design of pavement [2] but usual flooding duration is more than 4 days in Bangladesh and may increase in future. Due to increase in precipitation and flooding duration pavement will remain in saturated condition for longer time. Saturated layers of the pavement cannot bear the wheel load of the vehicle. So, pavement life will reduce and road maintenance cost will be increased. Moreover, increase in pavement temperature will affect the functioning of the asphalt layer and will reduce the pavement life.

However, it is important to quantify the pavement damage done by moisture. If quantification of the damage can be done it will be possible to show the significance of the problem. Since road infrastructure is the main mode of transport of goods and passengers in Bangladesh, it should be safe against adverse climate change effect. Moreover, a developing country like Bangladesh has a limited budget allocation for road construction and maintenance. So, road design, materials selection, and traffic loading should be such that road construction and maintenance become economic and durable.

The study has attempted to quantify the effect of moisture for a typical national highway with consideration of vehicle overloading. In Bangladesh, vehicle overloading is common as mentioned in the road master plan [3].To predict the life of the flexible pavement due to changes in saturation period, the study has adopted mechanistic-empirical (M-E) approach. However, dynamic effect of entrapped water due to vehicular movement is not considered in the study. In this study mechanistic analysis was done with a software GAMES (General Analysis on Multi-layered Elastic system). GAMES provide strain values at critical location of the pavement. Pavement life is then predicted by using empirical model of Asphalt Institute with the critical strain values. Finally it has suggested probable solutions to fight against the moisture effect.

METHODOLOGY

Moisture Effect on Pavement

Finding moisture effect on pavement is based on measuring the damage occurred during flood by a standard axle. Due to flooding, stiffness values of layers reduce. With the reduced stiffness values of layers, pavements will exhibit less fatigue and rutting strength. It is reported that reduction of strength of pavement can be 1.5% to 50% within a short time [4] .This means damage induced by a

single axle during flood will be more.

It is found that Marshall stability value decreases and flow value increases with the increase of inundation period [5].Marshall stability-flow ratio decreases to approximately 38% of the initial after 30 days of inundation as shown in figure 1. Stability-flow ratio is proportional with resilient modulus (M_r) of asphalt concrete [6]. Table 2 shows M_r value of HMA for different saturation period. In this study, assumed M_r for dry condition is reduced according to stability-flow ratio for different saturation period

. Figure 2 shows, if saturation period is 30 days, subgrade CBR value reduces to 89% - 69% of the 4-days soaked CBR value depending on the condition of compaction [6]. CBR value for subgrade is linearly correlated with the resilient modulus [7]. So, resilient modulus of the subgrade modulus also decreases with inundation period. Additionally, resilient modulus for base and sub-base layer is assumed to be decreased with same rate as that of subgrade value. In this study, M_r values for dry granular layers are determined from standard CBR values by using correlation charts developed by Van Til. et al.[7].Table 1 shows the resilient modulus (M_r) values for different saturation period. Table 2 shows the typical layer thickness values for a national highway of Bangladesh.

Base	15	0.35
Sub-base	18	0.35
ISG	20	0.40
Sub grade	200	0.40

Axle Load

Standard single axle load for Bangladesh is 80 kN. However, to simulate overloading effect axle load of 100 kN, 120 kN, and 140 kN consecutively are also considered. Since overloading is a common practice in Bangladesh, it is taken into consideration while simulating saturation effect. Tire pressure for the study is considered to be 0.5 Mpa

Damage by a Standard Axle

Two failure mechanisms are considered to determine the damage done by a standard axle load. One is fatigue and another is rutting failure. To measure the pavement life, critical strain values are determined by general analysis of multi-layered elastic system (GAMES) software. Following steps have detailed the approach:

1. Resilient modulus (MR), Poisson's ratios, layer thicknesses and layer interface slip values, wheel load and tire pressure are needed as inputs to run GAMES.
2. To determine the fatigue and rutting life of the pavement, tensile strain value at the bottom of the asphalt layer and compressive strain value at the top of the subgrade layer as shown in Figure 3 is calculated first by GAMES. After getting the strain values for critical location of the pavement layers, life was predicted by Asphalt Institute model [8], [9].

$$N_{f_1} = 0.0796 {\varepsilon_t}^{-3.291} {E_1}^{-0.854} \quad (1)$$

$$N_{f_2} = 1.365E-07\varepsilon_v^{-4.477} \quad (2)$$

Where N_{f_1} = allowable number of load repetition to prevent fatigue cracking, N_{f_2} = allowable number of load repetition to prevent rutting cracking, ε_t = tensile strain at the bottom of Asphalt layer, ε_v = compressive strain at the top of sub-grade layer, E_1 = elastic modulus of asphalt layer.

Moreover, the damage (D_i) caused by each application of axle load is given by:

$$D_i = 1/N_i \quad (3)$$

Where N_i is the minimum number of load repetitions required to cause either fatigue or rutting failure.

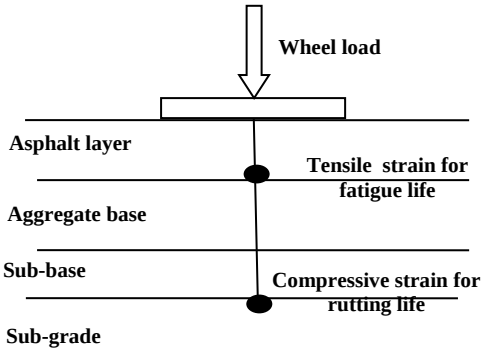

Fig. 3: Critical location of strain values for analysis.

RSULTS AND DISCUSSIONS

Moisture Effect on Pavement

From the Mechanistic-Empirical (M-E) analysis it is found that fatigue failure governs for the typical pavement of the national highway of Bangladesh as shown in the figure 4. Fatigue damage by a single axle is considered for making critical decision in this study as it is higher than that of rutting.

Figure 5 shows damage by a single standard and overloaded axle for different saturation periods. Here, damage are normalized by the damage value of a standard axle load during dry period. It is found that damage by a standard axle during 30 days of saturation period is approximately 3 times than that of dry period. Other study reveals that, the relative damage due to a single axle load for wet sections varies from 5 to 70,000 times in comparison to drained sections [10]. In this study it is found that if axle is overloaded by 6 ton the damage is approximately 20 times higher than that of dry period.

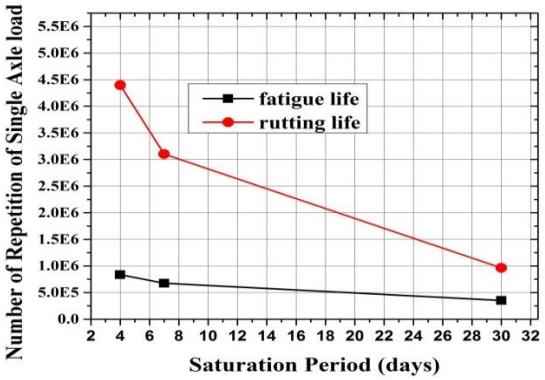

Fig. 4 Comparison between fatigue and rutting life of the pavement.

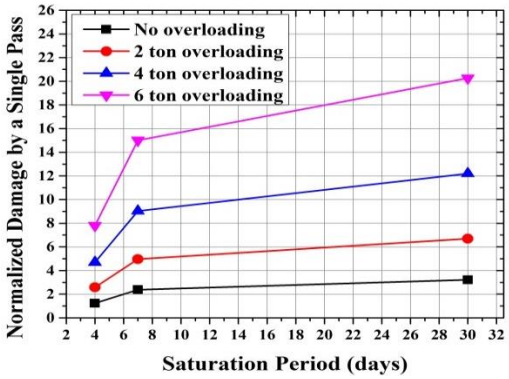

Fig. 5 Effect of saturation and overloading on pavement.

Figure 6 shows a standard axle in saturation period causing additional damage to the pavement. Actually, layer's stiffness reduces during saturation condition and hence the standard load causes additional damage. As a result, even if a standard axle load is allowed to pass during saturation condition pavement life will reduce drastically. However, we can prevent the pavement from losing its life by allowing a load less than the standard axle load so that it does not cause additional damage to the pavement.

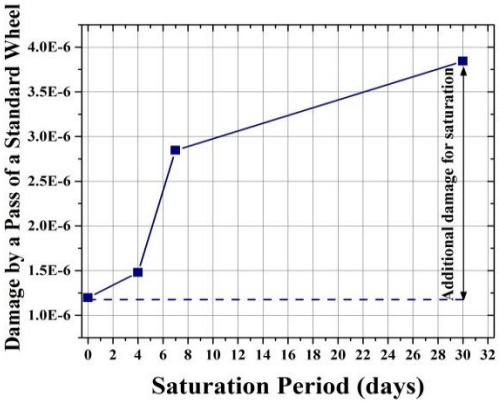

Fig. 6 Damage done by a single pass of a standard wheel load.

Figure 7 shows relationship between wheel load and damage for different saturation period of the pavement. By using the fitted equation shown in the figure 7, it is found that for a saturation period of 30 days a wheel load of approximately 28 kN causes the same damage as that of a 40kN wheel load in dry condition. If 70% of the standard axle load is allowed for the pavement with 30 days saturation period, it will not create additional damage. Figure 8 shows the allowable axle load for different saturation period. If axle load is restricted to the allowable limit until the dry back period of the pavement, its life will not reduce at all.

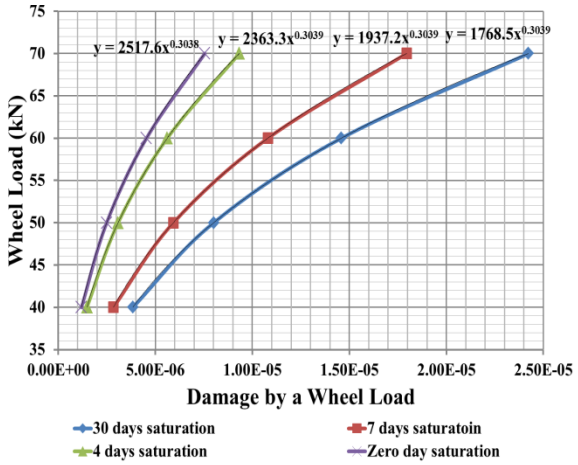

Fig. 7 Load damage correlation for different saturation periods.

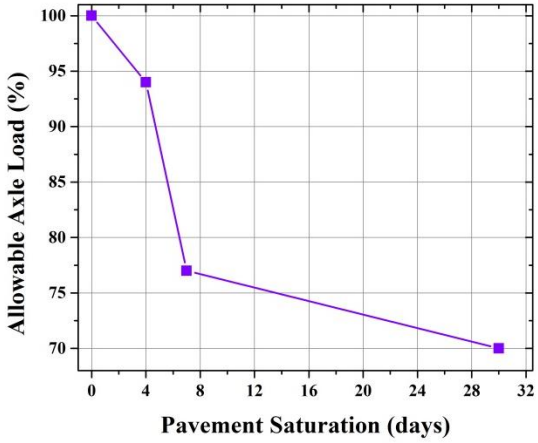

Fig. 8 Allowable axle load during saturation period.

CONCLUSION

The study has made an attempt to simulate the effect of climate change on roads of Bangladesh. It has developed a methodology for finding the effect of moisture by M-E method. It has also proposed a methodology to impose axle load restriction on pavement to minimize the moisture effect. The study concludes with the following findings :

1. Damage by a standard axle load to the 30-days saturated pavement is approximately 3 times of damage to the dry pavement.
2. However, damage by a 6 ton overloaded axle to the 30-days saturated pavement is 20 times of that by a standard axle to the dry pavement.
3. Reduction of the standard axle load will be necessary during saturation period to keep the pavement design life unaffected. For a sturation period of 30 days, 70% of the standard axle load should be allowed to minimize the effect of pavement saturation.
4. Moreover, overloading should be totally restricted during pavement saturation period.

QUANTITATIVE EVALUATION OF WATER POLLUTANT LOAD FROM KINOKAWA RIVER BASIN BY HIGH-FREQUENCY WATER QUALITY OBSERVATION

Hiroto Tanouchi[1], **Akihisa Imoto**[1], **Kouichi Ishiura**[1] and **Nobuyuki Egusa**[1]
[1]Faculty of Systems Engineering, Wakayama University, Japan

ABSTRACT

In the Kinokawa river basin, as same as other watersheds around the world, excess runoff of nutrients to the ocean mainly due to human activities has become an environmental issue. This study conducted high-frequency total nitrogen (TN) and total phosphorus (TP) monitoring at several monitoring posts along the Kinokawa river in the Kii peninsula, Japan in order to evaluate water pollutant load from the basin quantitatively. The water sampling has been conducted about 90 times for over a year from May in 2018 at several monitoring posts set along the downstream of the Kinokawa river. In the calm or the drought periods, TN concentration at Kinokawa river mouth were basically about 0.8 ~ 1.1 mg/L, TP were under 0.05 mg/L. On the other hand, TN concentrations could exceed 5.0 mg/L after one of the most intense storms, it was shown the TN concentration had a tendency extremely to rise especially in flooding condition. This tendency was similar in TP. In addition, the results of analysis including flow rate indicated that about 65% of the nitrogen load and 80 % of the phosphorus load from the basin was generated during a few and heavy flooding which were included in 5 % flow exceedance probability. These results suggested that almost all pollutant loads from basin was occurred in flooding conditions. It was also implied an improvement of the prediction accuracy of nutrient runoff simulation during flooding condition was vitally important.

Keywords: Pollutant loads, River water quality, Total nitrogen, Flooding, Kinokawa river basin

INTRODUCTION

Water quality conservation of rivers, lakes and ocean has still been a global issue. Therefore, a number of water quality observations and numerical analyses aiming at elucidating nutrients runoff mechanism has been conducted around the world. Donald and William (2001) showed that nitrogen flux from the basin to Gulf of Mexico was significantly increased in 1970s by using nitrogen concentration data of Mississippi river water during 100 years [1]. As studies targeting smaller spatial scale, [2] compared pollutant loads of pre-European settlement with ones of current into Great Barrier Reef by using numerical model. They utilized ten kind of pollutant substances as indicators, almost all substances increased over 5 times from pre-European settlement. We also evaluated water quality and pollutant loads targeting in Kinokawa river basin, which is also the target basin in this study, by using numerical water-nutrient runoff model [3]. This study showed the indicator "2-MIB" tended to increase when total phosphorus (TP) concentration exceeded 0.02 mg/L. It was concluded that the measures to combine TP mass load reduction with an increase in river flow rate could reduce TP concentration to less than 0.015 mg/L and prevent increases in 2-MIB in tap water.

As well as long-term fluctuation characteristic, extreme events like storm and resulting floodings are also important in river and ocean water quality. Several studies indicated almost all nutrients flux were generated by floodings. [4] conducted stormwater nutrients monitoring at the monitoring posts distributed whole Singapore. In [4], it was ascertained parklands could become main nutrient sources, including TN, TP and TSS in urbanized area. Although [5] also targeted in urbanized watershed in Korea to indicate mainly source of nutrients based on water quality monitoring, they concluded it was difficult to determine the non-point source by specific characteristics such as land cover.

These studies suggested nutrient runoff mechanism driven by storm has not explained well still now. In order to reveal the mechanism of nutrient runoff, there remains a need for an accumulation of nutrient monitoring data in a various of basins. In addition, former studies to evaluate flooding influence mainly targeted on small/urban scale runoff phenomena, water quality monitoring data including flooding condition on the watersheds with middle or large spatial scale (>1000km^2) is insufficient.

In this study, firstly we conducted high-frequency water quality observation in downstream of Kinokawa river in order to accumulate vital data to understand the system of nutrient runoff. River water was sampled manually once every three or four days at four observation points on bridges. Then we estimated relationships between water volume and

TN/TP concentrations. Finally, the estimated river flow rates were multiplied by estimated concentrations of TN and TP, we calculated the all nutrient loads from the Kinokawa river basin.

STUDY AREA

Figure 1 shows the land use in 2014 and observation points to sample river water. The length of Kinokawa river is about 136km, total watershed area is about 1750km^2. The basin extends from east to west, and after passing through the mountainous area in the eastern area (central massif of Kii peninsula), the river flows to the east and flows into the Seto Inland Sea. Majority of land use is forest (about 75%), followed by agricultural fields (farmland and rice paddy fields were 10% and 6%, respectively). Urbanized areas are concentrated downstream area, and the ratio of cities to the total is 9%. We conducted 80~90 times of water sampling from Musota bridge, Iwade bridge, Isaka bridge (across Kinokawa main river) and Kitajima bridge (across Kishi river, a large branch of Kinokawa river). In addition, we sampled water at the mouth of small canal and tributaries located between Musota and Iwade (1) ~ 4)) on 2018/6/15 in order to evaluate the influence of small water flows.

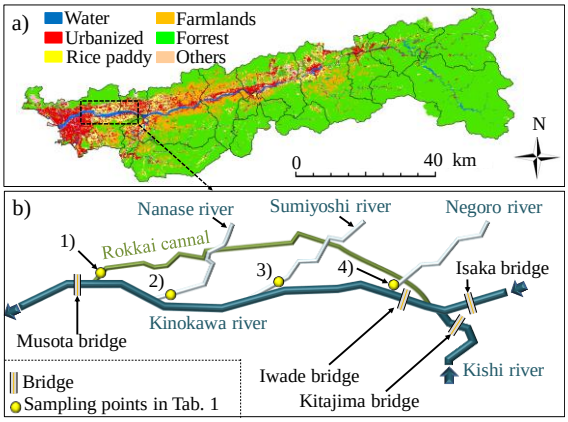

Fig. 1 a) Land use map in Kinokawa river basin based on Land Use Fragmented Mesh Data [6] and b) a thematic map indicated flow paths of Kinokawa main river and branches, canal, bridges and points we conducted water sampling. The numbers of sampling points were corresponding to ones of Tab. 1.

METHODOLOGY

River Water Sampling

Samplings were performed by lowering tinplate bucket from center of Musota bridge, Iwade bridge, Isaka bridge and Kitajima bridge. Drowned water by the bucket was put in polyethylene bottle, immediately installed in a cooler and kept to cold. Here, temperature in the cooler was kept about 2 ~ 8 degrees Celsius. Sampled waters were chemically analyzed basically within 4 hours after sampling. In this article, we mainly analysed and discussed about nutrients concentrations observed at Musota and Iwade.

Measurement of TN and TP concentrations

Figure 2 shows equipment for chemical analysis to measure TN concentration and TP concentration. TN and TP concentrations were estimated by TNP-10 produced by TOA DKK [7]. TN concentration was measured based on peroxodisulfate 120°C decomposition method [8]. In this method, firstly all nitrogen compounds are replaced into nitrate ion. Secondly nitrate ion is reduced to nitrite ion. Then, sulfanilamide added into chemical sample is diazotized by nitrite ion. Finally, the absorbance of the red azo compound formed by adding N-1-naphthylethylenediamine to the sample is measured to estimate the concentration.

Fig. 2 Equipment for chemical analysis to measure Total Nitrogen (TN) concentration and Total Phosphorus (TP).

TP concentration was measured based on peroxodisulfate 120°C decomposition method [8]. Here, all phosphorus compounds are firstly oxidized to phosphate ion by added acidic reagent to the sample. Then a mixed solution of ammonium molybdate and ascorbic acid is added to the sample. Finally, the absorbance is measured to determine the concentration of TP.

The detection limits for TN concentration and TP concentration in this device are 0.2 mg / L or more and 0.05 mg / L or more, respectively. Detected values below these limitations are untrustworthy.

Flow Rate Estimation

In this study, hourly river flow rate was estimated by using hourly time series data of water level and rating curve. hourly water level data observed at Funado (almost at the same place as Iwade) water level observation station has been provided by

Japanese ministry of land, infrastructure, transport and tourism [8]. The rating curve at Funado station was also developed by the ministry, we used this curve directly. Although the rating curve is state of the art we can obtain, it was optimized to calculate 2016's flow rate. In addition, the scope to apply this curve was obviously stated, heavy flooding that water levels exceed 2.93m and strong drought with water levels below -1.25m out of applicable. However, the rating curve was also applied in this study to calculate the flow rate under the un-applicable range because of no other way to estimate flow rate. Note that errors of flow rate under extreme storm/drought events could be large.

Estimation of Flow Rate - Concentration Relationship

We created regression lines of flow rate and TN/TP concentrations based on the assumption that there is a linear relationship between the flow rate at Funado and the TN and TP concentration at Iwade and Musota, respectively. Although this assumption might not appropriate for expression of nutrient runoff, we adopted it because of model simplification. This obvious weak point to express relationship between flow rate and nutrient concentrations should be discussed in future study. The reason why we used Musota's TP concentration data instead of Iwade's data here was because Musota had more data, and data on extreme phenomena such as floodings and droughts were also abundant.

Annual Pollutant Loads Estimation

Hourly TN and TP pollutant loads from Kinokawa river basin for target period were calculated by multiplying the flow rate at Hunado by the nutrient concentrations estimated by the regression lines. Secondly, we created flow duration curves of water quantity, hourly loads of TN and TP. Then, we, we estimated TN load and TP load that runoff in the top 5% of the flow rate in the target period, and calculated the ratio of them in the all pollutant loads. By this comparison, we evaluated flooding impact in total nutrient loads quantitatively.

RESULTS AND DISCUSSION

Temporal Variation of TN/TP Concentrations

Figure 3 shows flow rate at Funado station and TN, TP concentrations of river water at Musota bridge and Iwade bridge from 2018/5/15 to 2019/6/10. Average TN concentration for whole observation period at Musota and Iwade were 1.00 mg/L and 0.87 mg/L, respectively. Although TP was monitored simultaneously, TP concentrations were basically under detection limit. Therefore, we discussed about TN concentrations here.

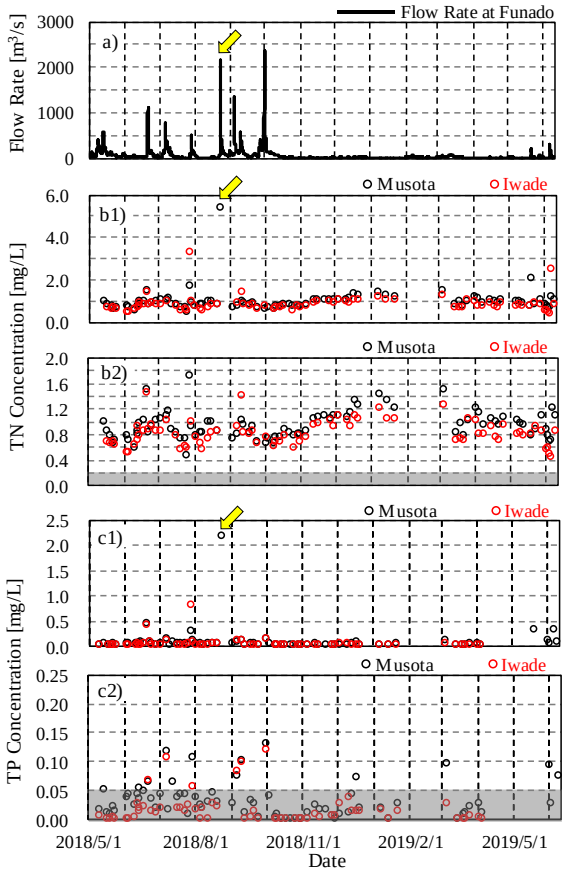

Fig. 3 a) Flow rate estimated at Funado water level station, b1) & b2) TN concentrations observed at Musota bridge and Iwade bridge, c1) & c2) TP concentrations observed at Musota bridge and Iwade bridge. b2) & c2) are engaged figures of b1) and c1). Yellow arrow shows the observation on 2018/8/24. Grey masks in b2) and c2) indicate under detectable limitations.

Fig.3 b2) indicates Musota's TN concentrations were chronically about 0.1~0.2 higher than Iwade's ones on the same date. This tendency implied the possibility that inflows with high TN from small tributaries or agricultural canal influenced total environment on Kinokawa river. Therefore, we conducted additional TN concentration observations at the mouths of these tributaries and canal. Fig. 1 also shows a map of tributaries/canal between Musota and Iwade. Table 1 shows TN concentrations observed at the mouth of each tributary or canal on 2018/6/15, all of them seems to be sampled under calm condition. The concentrations of TN at Musota and Iwade on June 15, 2018 were 0.98 mg / L and 0.79 mg/L, respectively. Although all TN concentrations of them were higher than ones of main Kinokawa river, Rokkai canal located at about 500 m

upper Musota bridge was especially higher than the others. Therefore, inflow from Rokkai canal mainly could influence for Kinokawa river environment.

Table 1 TN concentrations observed at 1)Rokkai canal, 2)Nanase tributary, 3)Sumiyoshi tributary and 4)Negoro tributary. 1)~ 4) were sampled at the mouth of them on 2018/6/15.

	1)	2)	3)	4)
Sampling time	8:28	8:45	9:00	9:17
TN[mg/L]	2.00	1.27	1.48	1.76

Rokkai canal supplies water for rice paddies located in right bank of the Kinokawa Plain. The canal was opened only when irrigation period (2018/6/1~2018/9/30), no water flowed except this perido. The upstream end of the irrigation canal is located about 500 m upstream of the Iwade Bridge, and it is designed that water of 4.96 m^3/s is always withdrawn from the Kinokawa river. Although the exact flow rate has not been confirmed, a portion of the water irrigated by the rice paddy fields will return to the canal and finally re-enter the Kino River at 1). Such hypothesis could be reasonable, however, it was difficult to prove them quantitatively due to the lack of TN observation data so far. In addition, since the discharge data of channel and tributaries are also insufficient either, data accumulation of TN concentration and flow rate to assess of agricultural activities in the Kinokawa plains will be necessary.

Fig. 3 also shows that there were the data observed extremely high concentrations of TN and TP, such as 2018/8/24 (Yellow arraied points). High TN and TP concentrations were tended to be generated when flow rate at Funado were getting over 200m^3/s, which was equivalent to 3 times of average flow rate in target period (62.9m^3/s). Figure 4 shows relationships between flow rate at Funado and the concentrations. Because the number of TN concentration data was totally 90, we considered TN data could be analyzed statistically here. On the other hand, TP concentrate data at Iwade whose values exceeded 0.05 mg/L (detection limit) were only two. Therefore, we utilized TP concentration data at Musota insteadly, the number of Musota's TP was 13.

Although there was no obvious relationship between TN concentrations and the flow rate in calm condition (Flow rate < 100 m^3/s), we could confirm that the concentrations rises with increasing the flow rate when it got over 100 m^3/s. A coefficient of determination between TN and flow rate was calculated as 0.46, it was met the significance level of 5%. The increasing tendency of concentration with the increase of flow rate was much stronger in TP than TN. A coefficient of determination between TP and flow rate was as high as 0.97. However, this unnaturally high coefficient could be influenced by the extremely high concentration observed in August 24, 2018 (red circle in Fig. 4 b1)). In addition, the evaluation by calculating regression line, the value of segment became -0.081. minus value in the segment can be inappropriate because negative concentration values could occur. Therefore, the coefficient excluding data observed on 2018/8/24 was also calculated, we obtained the value as 0.66. This value was also significant met the significance level of 5%.

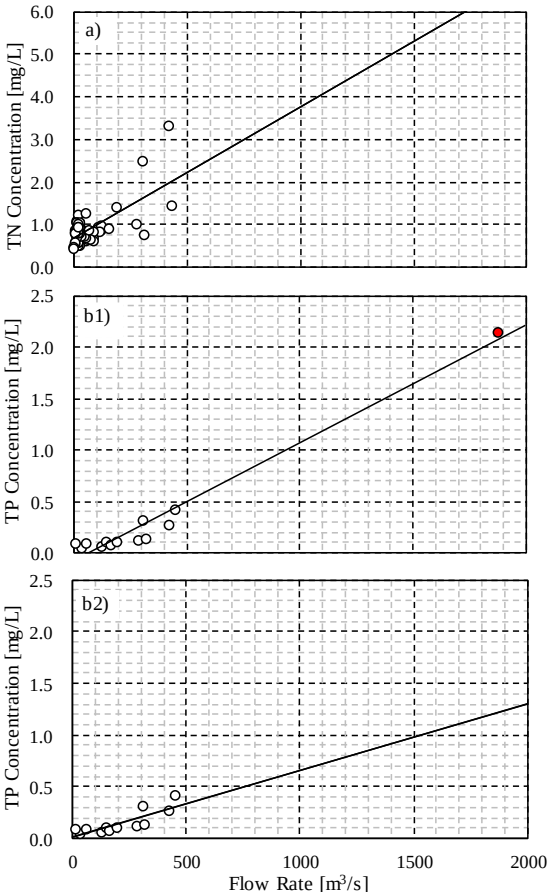

Fig. 4 a): Relationship between TN concentration at Iwade and flow rate at Funado. b1): Relationship between TP concentration at Musota and the flow rate. Although b2) also shows relationship between TP concentration and flow rate, extremely large value observed 2018/8/24 is excluded. Each figure has regression lines.

The tendency of this concentration rise could be considered caused by the increase in suspended solid in river water accompanying the increase in flow rate. Figure 5 shows pictures of sampled waters at Musota bridge and river flow at Iwade headwork which are located at 500m upstream of the Iwade bridge. They were taken on 2018/8/24 under flooding condition, indicated that river water contained a large amount of suspended solid such as soil particles, and the flow velocity looked large therefore these suspended solid was difficult to sink. Suspended solid have function as a nutrient carry, and it has been reported that this property in river water to be remarkable with

phosphorus than nitrogen [10]. In order to evaluate an influence of suspended solid, suspended phosphorus and suspended nitrogen contained in river water during floods should be measured separately from TN and TP. This is a future issue.

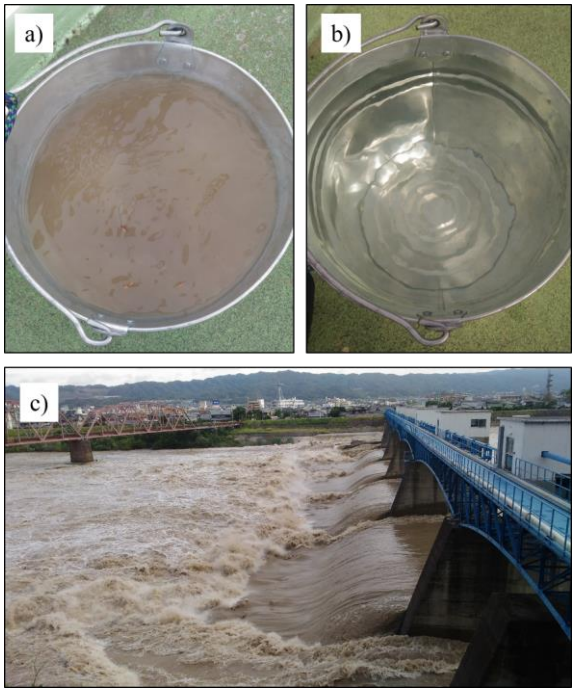

Fig. 5 a) River water under flooding condition sampled at Musota taken at 7:02 am, 2018/8/24. b) River water under calm condition sampled at Musota taken at 9:19 am, 2018/8/16. c) river flow at Iwade headwork on the same date as a).

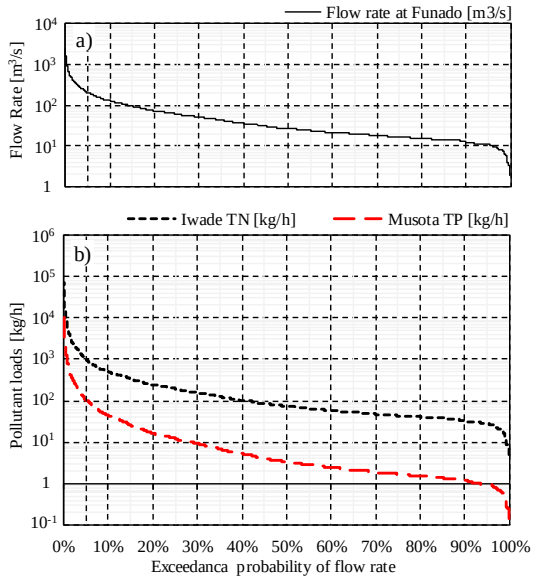

Fig. 6 Flow exceedance probabilities of a) flow rate, b) TN load and TP load.

Finally, we created regression lines between flow rate and concentrations. Relationship between TN at Iwade and flow rate at Funado was expressed as follows;

$$C_{TN} = 0.0031Q + 0.687 \quad (1)$$

where C_{TN} and Q are TN concentration at Iwade and hourly flow rate at Funado, respectively. Then, the relationship between the TP at Musota and flow rate at Funado became as follows;

$$C_{TP} = 0.0006Q + 0.019 \quad (2)$$

where C_{TP} is TP concentration at Musota. Both segments in (1) and (2) were larger than 0, it is guaranteed that the concentration is 0 or more in these equations even if little flow rate.

Annual Pollutant Loads Estimation

Figure 6 shows flow duration curves of the flow rate and pollutant loads of TN and TP, whose vertical axis are logarithmic. Both TN load and TP load were calculated by multiplying flow rates with TN and TP concentrations which were obtained by equation (1) and (2), respectively. In other words, these load calculations used estimated concentrations obtained assuming a linear relationship with the flow rate, the load amounts in this study are, as a result, proportional to the square of the flow rate. By analysis of fig.6, TN load and TP load were only about 150 kg/h and 15 kg/h when the flow rate was 100m^3/s whose excess probability was 10%. It was also shown, however, as excess probability of the flow rate decreases further, not only the flow rate itself but also the TN load and TP load more rapidly increased. This tendency could be caused that the loads proportional to the square of flow rate value because the loads were calculated by multiplying the concentration which were estimated by flow rate with the flow rate again. Whether such estimation is appropriate will be necessary to be discussed in the future. By a comparison TN with TP, the rapid increase in loads associated with floodings were more pronounced in TP than in TN, which is consistent with the characteristic that phosphorus was more likely to flow out as suspended solid.

Tab.2 shows the annual equivalent of TN and TP loads calculated by using fig.6. The annual equivalent of TN load was about 3300[t], and the sum of TN load on the flooding (included top 5% excess probability of flow rate) was 2100[t]. This result indicated that 65% of TN load runoff in the flooding condition. Sum of TP loads on the flooding was 326[t], which was equivalent to 80% of total annual TP runoff. These results suggest that accurate prediction of huge nutrient discharge during floods will be essential for quantitative assessment of nutrient discharge from the

basin.

Table 2 Total amount of annual TN, TP loads, the summed loads generated top 5% excess probability of flow rate, and ratios of Sum of top 5% / annual total loads.

	TN load	TP load
Annual total [t]	3263.6	408.4
Sum of top 5% [t]	2019.9	326.7
Ratio [%]	64.6	80.0

CONCLUSION

In this study, we conducted high-frequency water quality observation especially TN and TP aiming at quantitative evaluation of water pollutant loads from Kinokawa river basin. Results of the analysis based on TN and TP concentrations, flow rate of Kinokawa river and pollutant loads provided following considerations;

1) TN concentrations at Musota was chronically higher than ones of Iwade. The scales of agricultural canal and three tributaries flowing into Kinokawa river located between the bridges seems to be too small to impact on the environment of Kinokawa main stream. In order to understand the impacts of them, it will be necessary to accumulate quantitative data of flow rate and TN concentration.
2) In flooding condition, TN and TP concentrations in river water rapidly increased. It might be caused by increase of nitrogen and phosphorus attached suspended solid under flooding condition.
3) Almost all TN and TP loads were runoff in flooding whose flow rate were over 5 % flow exceedance provability. It was strongly suggested an accurate understanding of the nutrient discharge mechanism during floodings are essential for understanding the nutrient discharge phenomenon to the sea area.

Finally, we stress the limitations of this research and discuss some remaining future issues. It should be emphasized that river water quantity in heavy flooding and strong drought condition might include large errors because of out of scope of H-Q equations. Especially there was a possibility the results of this study might be affected, if the estimated flood flow rate contained large errors. In addition, in calculation of the annual runoff loads of TN and TP, we made the strong assumption that these concentrations are linearly related to the flow rate for simplifying the models. Further work is necessary to investigate how the approach can be improved in this respect.

ACKNOWLEDGMENTS

In this study, H-Q curve equations were provided from Wakayama office of Rivers and National Highways, Kinki Regional Development Bureau, Japanese ministry of land, infrastructure, transport and tourism. We express our gratitude, here.

VARIATION OF STRAIN DURING THE CONSTRUCTION OF AN INCREMENTALLY LAUNCHED CONCRETE BRIDGE

Norisham Ibrahim[1], and Norhayati Abdul Hamid[2]
[1,2]Faculty of Civil Engineering, Universiti Teknologi MARA, Malaysia

ABSTRACT

Incremental launching is an alternative method of construction for medium span prestressed concrete bridges. However, the design and analysis of the concrete box girders are complicated due to the construction process and many other factors including the creep and shrinkage behaviour of the structure during and after the construction is completed. To gain better understanding of the strain variation, an incrementally launched prestressed concrete box girder bridge was instrumented with several vibrating wire strain gauges. The installation of vibrating wire strain gauges were done as not to miss the earliest possible data. The locations of vibrating wire strain gauges were selected to evaluate strains at critical sections. Strain variation at ten minute intervals captured during the launching operation is illustrated. Variation of strain due to other major construction activities such as concrete pouring and stressing of tendons are also shown. As expected, the abrupt change in strain can be seen immediately after launching

Keywords: Incremental launching, Vibrating wire strain gauge, Prestressed, Strain

INTRODUCTION

Incremental launching [1] construction method has become competitive since many years ago due to the advantages offered over the conventional construction method such as reduction of environmental constraints and use of road access. It also eliminates the distance between the casting yard (where a cast of segments take place) and the construction site. By using an incremental launching technique, it is essential for a bridge designer to understand the construction technique and how the construction technique affects the design parameters.

For an incrementally launched bridge, the location of a particular concrete segment changes from the beginning till the end of the construction. As a result, at any point on the concrete segment the value of stress vary throughout the construction process. Change of stress is also accompanied with shift in of concrete age and environmental condition. Since there are design parameters which are dependent on stress value, concrete age and environmental condition, the determination of these parameters has become very complicated. Among the design parameters which are highly influenced by concrete age and environmental condition are creep strain and shrinkage strain. Furthermore, the creep strain is also dependent on stress.

.

CREEP AND SHRINKAGE STRAIN

Both creep strain and shrinkage strain are critical parameters in the design of a prestressed concrete bridge, and these values must be predicted in order to be utilized in the design. The wrong prediction may cause the failure of the structure since these two parameters cause loss of stress force in the prestressing tendons as shown in [2] and [3]. Loss of stress force affects the capacity of the prestressing tendons installed in the concrete segments which finally affect the whole bridge structure.

Development of creep strain sand shrinkage strain is complicated as explained in [4] and there are many uncertainties in the prediction as shown in [5] due to the influence factors which occur concurrently. The investigation of creep and shrinkage have been shown in many literatures as given in [6], [7], [8] and [9]. Recent papers about shrinkage include [10], [11] and [12] and [13]. Many prediction models have been developed and investigated as given in [14], 15 and [16] in order to better predict the creep strain and shrinkage strain values. The development of creep prediction model is in the separation of the shrinkage prediction model and vice versa. However, in the real structure, the creep strain and shrinkage strain occur simultaneously and can only be measured in the form of total strain.

Monitoring the strain variation during and after construction is an excellent opportunity to better understand how the strain varies when exposed to the change of stress, concrete age as well as the environmental condition. The result may help the designers to better predict the values of creep strain and shrinkage strain which are very important in the design of a prestressed concrete bridge. Therefore it is a great opportunity to have Tauranga Harbour Link

(THL) installed with strain gauges in the concrete segments in order to monitor the concrete strain during and after construction. The monitoring system of THL has been produced in [17]. Several figures are reproduced here for clarity.

DESCRIPTION OF THL

THL is a bridge in New Zealand constructed by incremental launching. The bridge alignment is a circle situated on an inclined plane with a radius of 682.4 m. The Reduce Level (RL) of the circle centre is -86.061 m. The RL for Abutment A (AA) and Abutment B (AB) are 5.377 m and 3.917 m respectively. The total horizontal length is 467 m with 12 spans altogether built up by 23 box girder segments as shown in Figure 1(a). Length of Segment 1 (S1) and Segment 23 (S23) is 23,753 mm while the length of Segment 2 (S2) to Segment 22 (S22) is 19985 mm. Height (H) of the segment is 2700 mm. Length of span 1 (L1) and span 12 (L12) is 33.75 m while the length of span 2 to span 11 (L2 to L11) is 39.97 m. The typical cross section is shown in Figure 1(b). The view is from AA towards AB. The top 450 mm of the box girder is called deck slab while underneath of the deck slab is called soffit slab.

CONSTRUCTION OF THL

The construction activities may be divided into 6 major part namely installation of reinforcement for soffit slab, pouring of concrete for soffit slab, installation of reinforcement for deck slab, pouring of concrete for deck slab, stressing of tendons and launching of segments. Using incremental launching, all the box girder segments were cast in situ on one side of the waterway, in this case at AA. The cast area is called a Casting Shed (CS). Once a new segment was completed, the whole segment(s) was pushed from AA heading to AB leaving the Casting Shed empty. The emptied Casting Shed was then used to cast a new segment.

This process was repeated until all the box girder segments were completed. All the segments are connected to each other by reinforcement steel and prestressing tendons. As shown in Figure 1(a), the identification numbers of piers and segments are according to the cast sequence. The first box girder and pier cast were numbered as Segment 1 (S1) and Pier 1 (P1) respectively. However, when the bridge was completed, Segment 1 is located on AB while Pier 1 is situated close to AA. The launching activities may be illustrated as given in Figure 2.

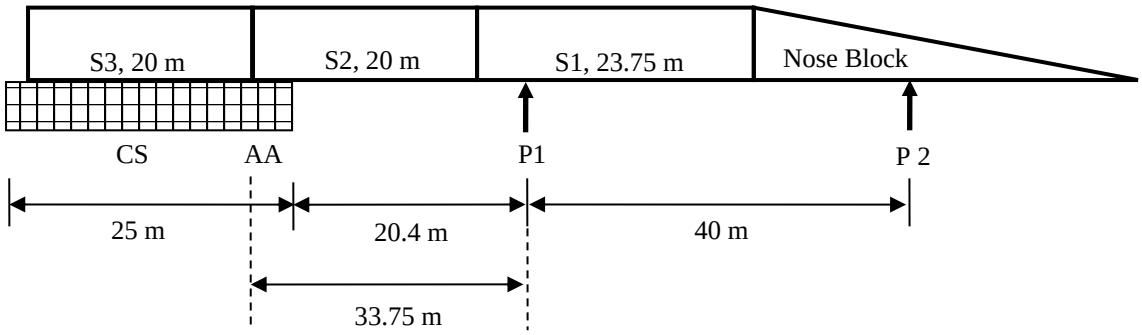

Fig. 2(c) Location of segment 1, 2 and 3 after second launching

MONITORING SYSTEM OF THL

The instrumentation system was based on [18]. Other researchers include [19] and [20]. One of the objectives to instrument THL was to measure concrete strains during and after, construction of the high strength concrete post-tensioned box girder bridge. The instruments used to measure the strain are vibrating wire strain gauges (VWSG). The segments instrumented are segment 15, 16, 17 and 18. According to the construction sequence, the first installation was done in segment 15, followed by segments 16, 17 and 18. There are four gauges in a segment. Location of the gauges are shown in Figure 1 as Point A, B, C and D. In segment 15 the gauges are known as BL15, BR15, TL15 and TR15 respectively. The bottom VWSGs were located at the depth of 300 mm from the bottom of the concrete face while the top VWSGs were positioned at 420 mm from the top of the concrete face. The installation of the instruments was done as not to miss the earliest possible data because most of the creep and shrinkage occur early after casting [4]. However, due to several problems, data from the instrumented gauges could only be logged after certain days of age.

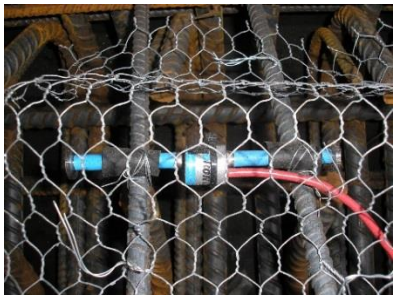

Fig. 3 A vibrating wire strain gauge

RESULTS

Results from BR15 is selected to be presented in this paper. The graph is plotted in the form that negative shows bigger compression than positive value. For clarity, the results are divided into several parts according to month. BR15 was connected to the datalogger on 24 Feb 09. At that time, the age of soffit was already 13 days and the segment already went through stressing and launching twice. As a result of launching, gauges BR15 was at about 9.6 m after Abutment A and 24.15 m before Pier 1 when the first data logged.

After the third launching, BR15 was at about 29.6 m after Abutment A and 4.15 m before P1. This strain variation after during and launching is shown in Figure 4(a). After launching 3, the strain is indicated as AL3. The next few launches are launching 4, 5 and 6. The variation of strain after each launching is indicated as AL4, AL5 and AL6 respectively.

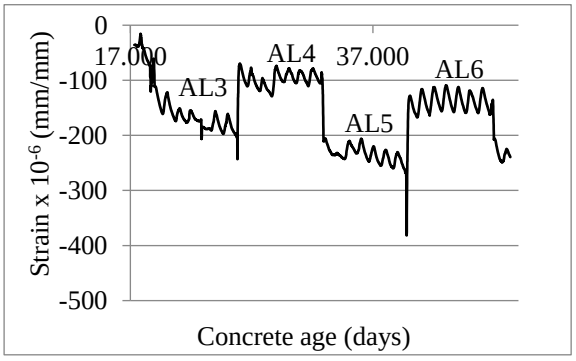

Fig. 4(a) Strain versus concrete age from BR15 recorded in March

Variation of strain during and after launching 7 and 8 are given in Figure (b). No more major launching was done after that because the segment already reached its final position. Any minor launch was only to correct if there was any misalignment of the bridge.

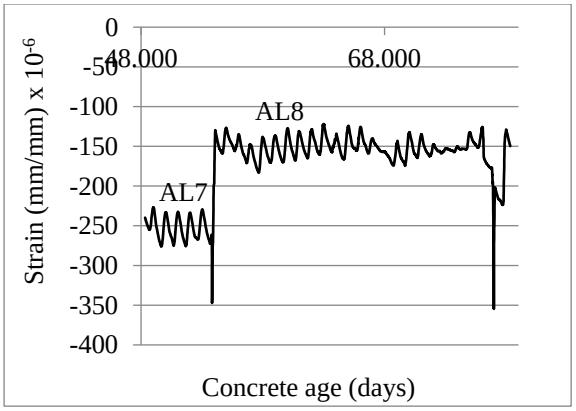

Fig. 4(b) Strain versus concrete age from BR15 recorded in April

CONCLUSIONS

In general, the location of BR15 may be divided into two major positions; close to pier or close to mid span. In comparison between these two locations, it is found that the soffit of the box girder is more compressed when it is located very close to the pier, as expected. The results would then be analyzed to study the creep and shrinkage behaviour of the bridge.

ACKNOWLEDGMENT

The author would like to acknowledge the help she received while conducting this research from Rudolph Kotze and Kelvin Reid of Transit New Zealand, Tim Grammer, Bryce Irving and Tony Pike of Fletcher Construction and Piotr Omenzetter, Jason Ingham, Noel Perinpanayagam, Sujith Padiyara and Mark Byrami of Auckland University.

MAPPING OF SEAWATER INTRUSION INTO COASTAL AQUIFER (CASE STUDY: PEKALONGAN COASTAL AREA, CENTRAL JAVA)

Muh. Irham Sahana[1], Roh Santoso Budi Waspodo[2], and Heriansyah Putra[3]
[123]Department of Civil and Environmental Engineering, Faculty of Agricultural Technology and Engineering, IPB University (Bogor Agricultural University), Indonesia

ABSTRACT

The intrusion of seawater has reported able to promote the degradation of groundwater quality. Seawater intrusion can be due to excessive exploitation of the groundwater or through natural phenomenon such as the tide floods. The inclusion of seawater in the land is not only being treated by the continued use of shallow wells but rather due to the phenomenon of seawater tide flood which is brought by the Bremi river and Tirto river causing a decline in quality of Groundwater. One of the areas that are affected by this disaster is Pekalongan City. Analysis of seawater intrusion in Pekalongan is conducted by referring to the decision of PAHIAA 1986 and the decree of Minister of Energy and Mineral Resources (ESDM). This study was conducted at 64 points spread across 4 sub-districts entire Pekalongan coastal area, which is 46.972 km^2. The result of this study shows that seawater intrusion in this location already affects the quality of groundwater is not depressed until it reaches a distance of 6.52 km from the seashore for the parameters of total dissolved solids (TDS) and electrical conductivity (EC), and 7.22 km from the seashore has been exposed to seawater intrusion based on the parameters of chloride ion. The magnitude of the safety zone decreased groundwater quality amounted to 23.324 km^2 or approximately 50% of Pekalongan area. Meanwhile, due to seawater intrusion, as much as 9.094 km^2 or 19% of the territory of the city of Pekalongan has been categorized into the damaged zone.

Keywords: Chloride, electrical conductivity, groundwater, seawater intrusion, total dissolved solids

INTRODUCTION

Seawater can influence groundwater quality and quantity through the intrusion and sea-level rise phenomenon. Seawater intrusion is the migration of seawater into freshwater aquifers under the influence of groundwater development [1]. Seawater intrusion is triggered by several factors, such as excessive pumping, land-use change, reduction in recharge because of global warming, and overtopping that caused by sea-level rise, storm surges, and tsunamis [1]. The increase in water withdrawals from the wells have caused unacceptable drawdowns and deterioration of the quality of water pumped by some of the wells. Fresh groundwater in the coastal aquifer is drained seas or lakes under natural conditions, and the interface line between fresh and salt water occurs. Massive exploitation of coastal aquifers also has an impact on the evolution of hydraulic gradient. This phenomenon is called seawater intrusion [2].

Seawater intrusion has a significant effect on human living, such as health disruption, decreasing of soil fertility, and buildings damaged, especially for people who live in coastal areas [3]. One of the coastal areas that have a big issue on the seawater intrusion is Pekalongan City. This city is located on the northern coast of Central Java Province, Indonesia. Tidal floods which have been inundating Pekalongan since 2013 became preliminary investigation that Pekalongan City experienced seawater intrusion, especially in North and West Pekalongan Districts. Fulfilling daily clean water needs by shallow groundwater wells also caused seawater intrusion in Pekalongan coastal area. The increasing exploitation of groundwater over time is thought to have resulted in seawater intrusion in aquifers in the coastal area. It also initiated the replacing groundwater in aquifers by sea water. This is indicated by the increasing number of population wells which has been turning into brackish. The objectives of this study are to investigate, analyze, and map the dispersion of seawater intrusion based on the relation between the electrical conductivity (EC), total dissolved solids (TDS), and chloride ion (Cl^-) to the distance of the well from the coast.

METHODOLOGY

This study was conducted in Pekalongan City, which has 4 sub-districts with the highest number of sampling points in the North and West Pekalongan Districts. These locations were the coastal areas and affected by the tidal flood. The primary and secondary data were used in this study. Firstly, the secondary data composed of the administrative map, Digital Elevation Map (DEM) data, and shapefile data of Pekalongan City were collected and used to obtain the sampling point.

The primary data of the unconfined groundwater samples were collected from 64 shallow wells, spread in 4 sub-districts. The measurements of the concentration of groundwater were conducted in the North and West Pekalongan Districts of 20 and 22 points, respectively. The distribution of the sampling point is depicted in Figure 1. The measurement was carried out using the instrument of AMTAST AMT03R to obtain electrical conductivity (EC), total dissolved solids (TDS), and chloride ion (Cl^-).

Furthermore, these results were analysed consider the coordinates of the location and distance from the coast. Then, a regression curve was made to improve the accuracy of the measurement results.

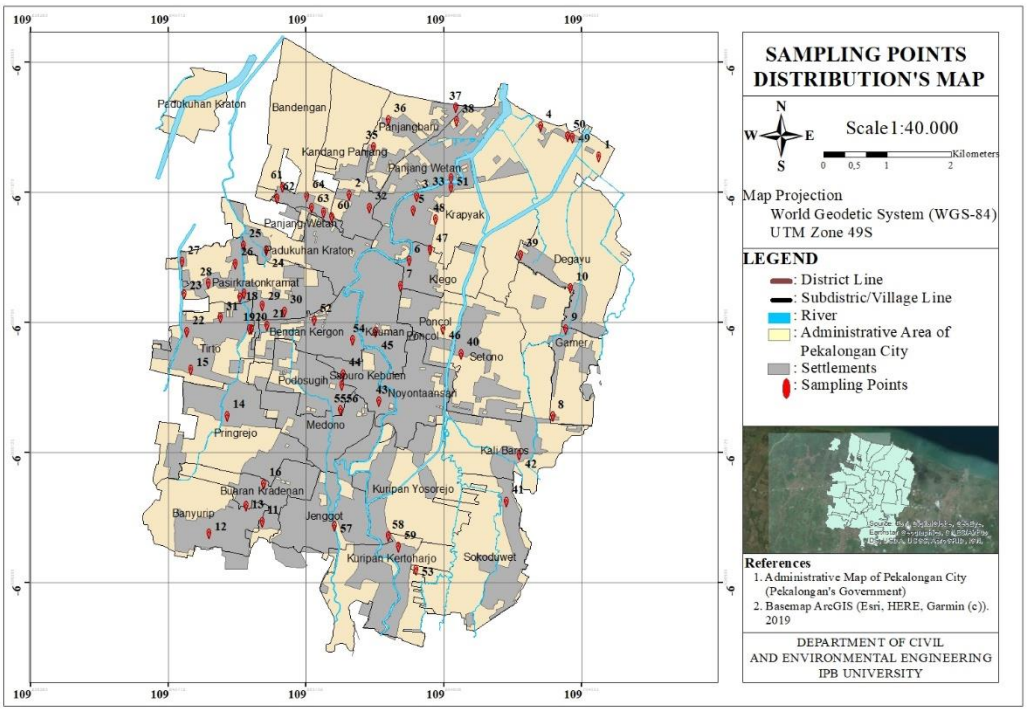

Fig. 1 Distribution of sampling points.

The dispersion map of seawater intrusion was based on the groundwater quality parameters which developed by refers to the Decree of the 1986 Ad Hoc Sea Water Intrusion (PAHIAA) Committee [3]. It contained 5 qualities of groundwater, namely, fresh, rather brackish, brackish, salty, and brine. Analysis of the data used was based on the values of electrical conductivity (EC), total dissolved solids (TDS), and chloride (Cl^-). The details of the classification of groundwater salinity level based on PAHIAA, 1986 were shown in Table 1.

Table 1 Classification of groundwater salinity level based on PAHIAA, 1986 [3].

Water Quality	TDS (mg/L)	EC (µmhos/cm)	Cl^- (mg/L)
Freshwater	<1,000	<1,500	<500
Rather brackish	1,000-3,000	1,500-5,000	500-2,000
Brackish	3,000-10,000	5,000-15,000	2,000-5,000
Salty	10,000-35,000	15,000-50,000	5,000-19,000
Brine	>35,000	>50,000	>19,000

Then, the alignment of the results from the plotting of coordinate data and the parameters of DHL, TDS, and Cl using Surfer 13 software. Furthermore, a general description of the zone of spreading seawater intrusion is seen through maps created using ArcGIS software.

The analysis was conducted using ArcGIS 10.4.1 software with the integrated distance weighted (IDW) method. The IDW method is a conventional interpolation method which considers distances as weights [4]. The interpolation refers to the flat distance from the data point (sample) to the block. The closer distance between the sample point and the block is estimated, the higher the weight is created [4]. The general weighting function is the inverse of the square of the distance, and the equation is used in the inverse distance weighted method. The advantage of this IDW method lies in the interpolation characteristics that can be controlled by limiting the input points used in the interpolation process. In addition, the selection of the IDW method compared to other interpolation methods such as spline and natural neighbor is that the use of IDW is able to interpolate values with considerable height differences [5].

RESULTS AND DISCUSSION

Groundwater quality parameters

The measurements of groundwater quality parameters show the highest concentrations of TDS, EC, and Cl^- are were 14330 mg/L, 21724 µmhos/cm, and 11360 mg/L, respectively. This value was obtained from Panjang Baru Village, North Pekalongan District with a distance of 440.220 m from the coast. Based on the classification of PAHIAA 1986, the quality of groundwater at this point was categorized to brackish water for TDS and EC parameters. Whereas, for the Cl^- parameter, it was categorized into salty water with concentration ranges from 5,000 to 19,000 mg/L. The difference of these parameters classification was due to salt ions (Cl^-) that affected the groundwater quality higher than the concentration of total dissolved solids (TDS) and electrical conductivity (EC) which were more influenced by metal elements in the groundwater. The amount of concentration obtained at that location was also influenced by the surrounding environment conditions which were flooded by tidal floods or sea tides so that salt and metals were more easily infiltrated and concentrated in the region.

Moreover, the smallest concentration was found in the Kuripan Yosorejo Village, South Pekalongan District, with a distance of 6,954.12 m from the coast. The magnitude of the concentration values of TDS, EC, and Cl^- were measured respectively at 142 mg/L, 213 µmhos/cm, and 104 mg/L. Based on this value, the quality of groundwater in the area was also classified as fresh water due to the TDS concentration was less than 1000 mg/L, the EC concentration was below 1500 µmhos/cm, and the salinity level was less than 500 mg/L. The result of measurements in West Pekalongan District, TDS concentrations ranged from 332 to 12356.8 mg/L, EC concentrations were 499 to 18740.02 µmhos/cm, and Cl^- concentrations were in the range 249 to 9798 mg/L. The highest concentration was obtained around the Tirto River, which was 3.65 km from the coast. It affected the pattern of the dispersion of seawater intrusion which tended to extend to the south. Then, the range of TDS values in North Pekalongan District ranged from 374 to 14330 mg/L, EC was in the range of 561 to 21724 µmhos/cm, and the chloride concentration was 281 to 11360 mg/L. In addition, the maximum concentration was found at a distance of 440.2 m from the coast. The result of this study indicated that the pattern of intrusion in North Pekalongan District was influenced by the phenomenon of sea tides due to its geographical location, which intersected the coast.

The results of measurements in West Pekalongan District had a range of TDS, EC, and Cl^- values of 314 to 844 mg/L, 471 to 1,266 µmhos/cm, and 235 to 633 mg/L, respectively. The distribution of the results of measurements of the concentrations of TDS, EC, and Cl^- in South Pekalongan District ranged between 142-460 mg/L, 213 to 690 µmhos/cm, and 104 to 345 mg/L. In general, the quality of groundwater in the South and East Pekalongan Districts were still feasible and classified into freshwater.

Correlation of TDS, EC, and Cl^- to distance from the coastline and Bremi river

The accuracy of the value of total dissolved solids, electrical conductivity, and chloride ion were evaluated based on measurement distance both from the shore and Bremi River to obtain the dispersion model entire groundwater quality parameters.

Correlation of TDS, EC, and Cl^- to distance from the coastline

The model distribution curves of TDS, EC, and Cl^- were presented using the logarithmic regression method because this regression method had the highest determinant coefficient or R^2 which approached the value of 1 (one) compared to the other regression methods. An intrusion of seawater was able to be predicted by connecting the values of TDS, EC, and Cl^- to the distance from the coastline. The results of the dispersion model are shown in Figure 2-4.

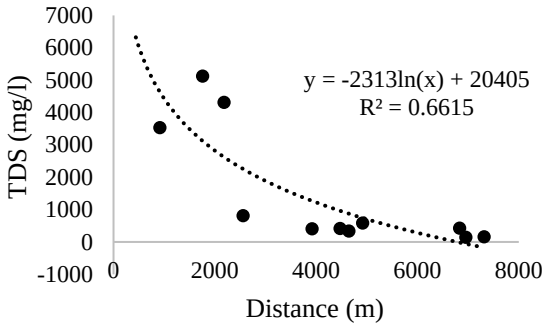

Fig. 2 Model dispersion curve of TDS in shallow wells to the distance from the coastline.

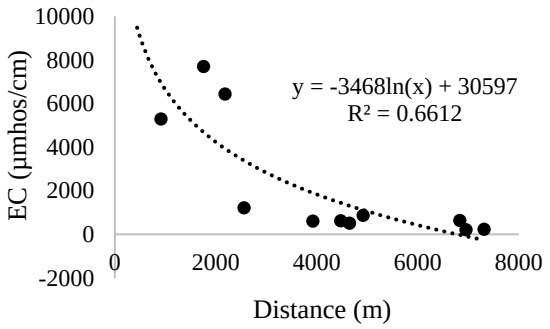

Fig. 3 Model dispersion curve of EC in shallow wells to the distance from the coastline.

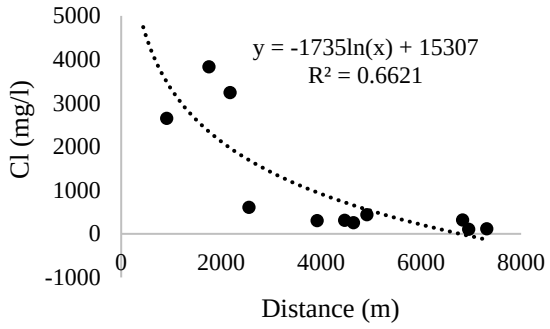

Fig. 4 Model dispersion curve of Cl^- in shallow wells to the distance from the coastline.

Based on observation from the curves above, the value of the three parameters decreased as the area farther away from the coast. The value of the equation obtained for the TDS relationship with distance was y = -2313ln(x) + 20405 with R^2 value of 0.6615. Then the equation value between the relationship of EC and Cl^- to the distance from the coastline respectively were y = -3468ln(x) + 30597 and y = -1735ln(x) + 15307, and the regression value respectively amounting to 0.6612 and 0.6621. Based on the value of the equation trend (R^2), the equations were not able to be used for regression analysis because R^2 value was less than 0,6750 or 67.50% [6].

Correlation of TDS, EC, and Cl^- to distance from the Bremi river

Although all parameters had been analysed from the coastline and had a strong relationship because R^2 had accuracy between 0.6-0.799 [7], but it couldn't be used for regression analysis. So, it was necessary to be re-analysis to the distance from Bremi river because of tidal floods. The model distribution curves of TDS, EC, and Cl^- were also presented using the logarithmic regression method to predict seawater intrusion model by connecting the values of TDS, EC, and Cl^- to the distance from the Bremi river. The dispersion curve and model are shown in Figure 5-7.

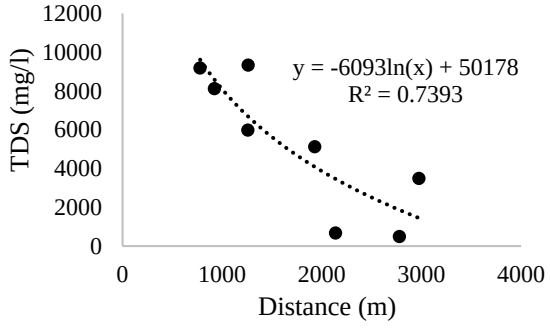

Fig. 5 Model dispersion curve of TDS in shallow wells to the distance from Bremi river.

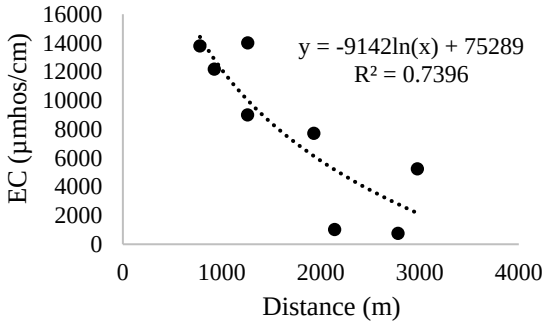

Fig. 6 Model dispersion curve of EC in shallow wells to the distance from Bremi river.

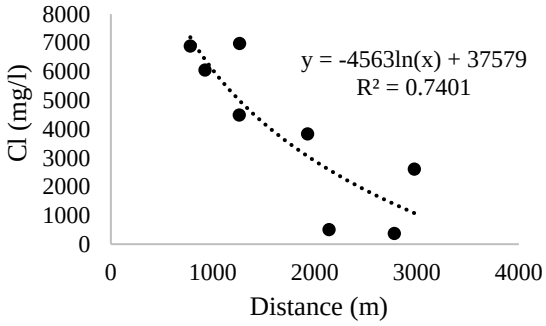

Fig. 7 Model dispersion curve of Cl^- in shallow wells to the distance from Bremi river.

Based on logarithmic regression analysis above, seawater intrusion dispersion in Pekalongan Coastal Area was mostly influenced by tidal floods phenomenon which was carried out by Bremi River. This analysis was proven by the accuracy of logarithmic regression analysis was 73.93% to 74.01%. So, it met the requirements that R^2 was suitable for regression analysis if it must be above 67.50% [6]. The value of the equation obtained for the TDS relationship with distance was y =-6093ln(x) + 50178 with R^2 value of 0.7393 or 73.93% for its accuracy. Then the equation value between the relationship of EC to the distance from the coastline were y = -9142ln(x) + 75289 and had an accuracy of 73.96%. While, the value of the equation obtained for the Cl^- relationship with distance was y = -4563ln(x) + 37579 with R^2 value of 0.7401 or 74.01% for its accuracy. Analysis was also conducted using linear regression, but it had smaller ratio of 0.7132 to 0.7139. Thus, the ratio in saline water was best described by logarithmic equation [11].

Correlation of TDS, EC, and Cl^- parameters

In addition, the three parameters also had a high correlation, so the measurement data which was used had high strength are shown in Fig. 8 to 10.

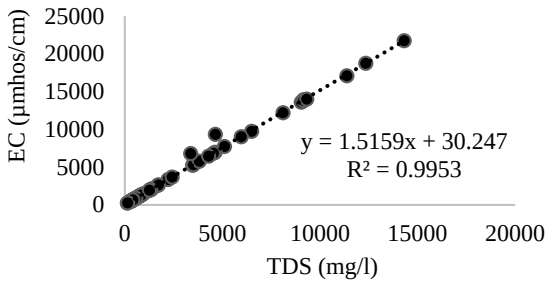

Fig. 8 Correlation curve between EC and TDS.

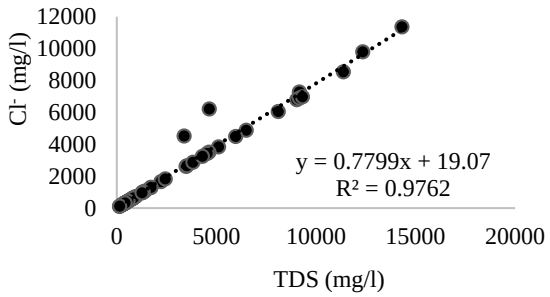

Fig. 9 Correlation curve between Cl^- and TDS.

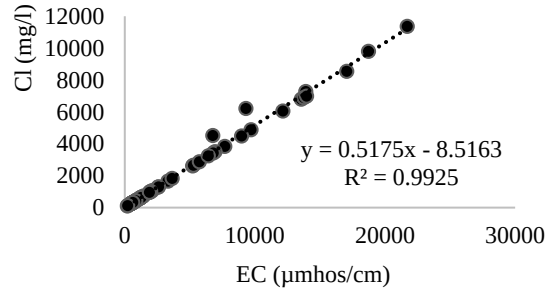

Fig. 10 Correlation curve between Cl^- and EC.

The correlation curve between TDS, EC, and Cl^- had a linear trend with R^2 values ranged from 0.9762-0.9953 or had an accuracy rate of 97.62% to 99.53%. This showed that the three parameters had a strong relationship and the data used was so accurate because it met the requirements that R^2 was suitable for regression analysis if it must be above 67.50% [6]. The linear regression equation for the correlation between TDS and EC was y = 1,5159x + 30,247 with accuracy reaching 99.53%. Then, the linear regression equation between TDS and Cl^- was y = 0.7799x + 19.07 with an accuracy of 97.62%. Furthermore, the equation between the value of EC and Cl^- was y = 0.5175x - 8.5163 with the accuracy of the data reaching 99.25%.

This difference indicates that the correlation of both parameters is strongly influenced by the EC values [10]. Whereas a high ratio between TDS and EC also has almost the same correlation (R^2 = 0.96) [10]. Even so, all the findings are in agreement with the conclusion drawn by McNeil and Cox (2000) [11] in which the obtained variation of TDS/EC ratio for freshwater can be vary 0.5 till ≥ 1.00 [11]. The type of freshwater is generally sodium, calcium, magnesium, bicarbonate type or calcium, sodium, bicarbonate, chloride type [11]. In line with this, it has been found that the most correlated major ions, especially to TDS, are chloride, sodium, and magnesium [12].

Dispersion Analysis of Seawater Intrusion

Dispersion pattern and flow direction of seawater intrusion

The pattern and flow direction of the dispersion of seawater intrusion were analyzed by the values of TDS, EC, and Cl^- carried out with Surfer 13 software. The analysis was performed using contour tools, the values of these three parameters combined with grid vector map tools to get the distribution and flow direction or flow net.

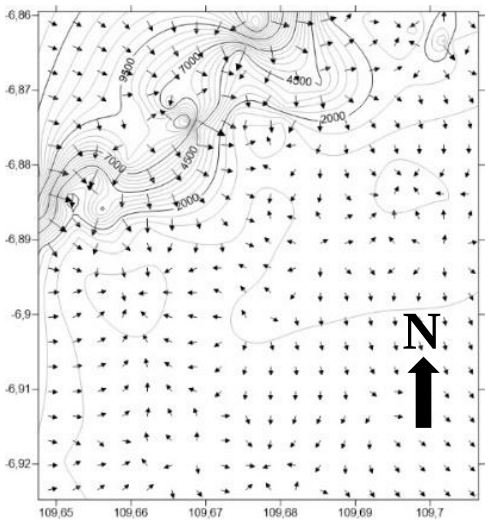

Fig. 11 Pattern and flow direction of TDS.

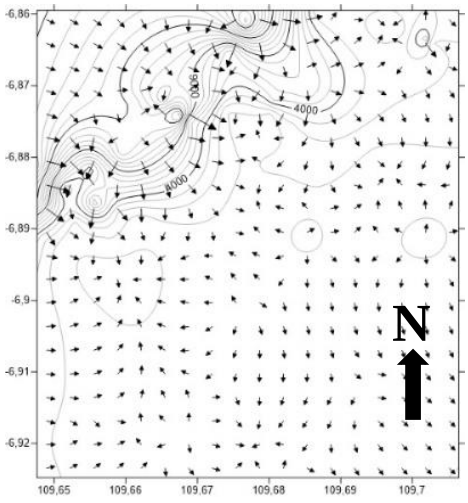

Fig. 12 Pattern and flow direction of EC.

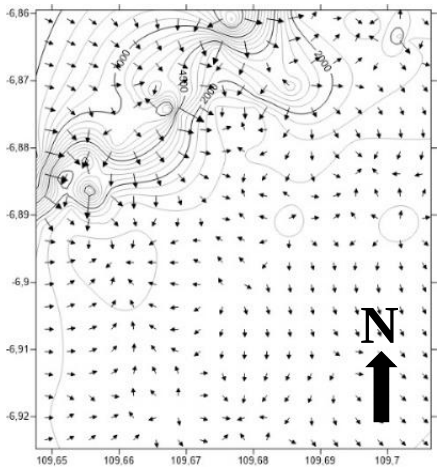

Fig. 13 Pattern and flow direction of Cl^-.

The dispersion pattern and flow direction were influenced by the distance and the magnitude of the measured parameter value. Based on Fig. 8 to 10, the direction of the dominant dispersion of seawater intrusion lead to the south or away from the coast and extended eastward. This meant that the concentration values of TDS, EC, and Cl^- decreased with the location of groundwater samples away from the coast and away from the Bremi and Tirto rivers in the western region. The pattern of the dispersion of seawater intrusion in Pekalongan City was influenced by tide flood or sea level rise, which was carried by Bremi and Tirto rivers. The inability of the river to accommodate sea tide loads due to river inflow discharge was smaller than the sea tide discharge, so seawater was intruded and polluted shallow groundwater. "Melo [5] states that seawater intrusion is not only influenced by excessive pumping (groundwater exploitation), but seawater intrusion is also able to be caused by changes in land-use, changes in recharge area conditions and rising sea levels to land due to global warming".

Mapping of seawater intrusion dispersion

Mapping of seawater intrusion dispersion based on the groundwater quality parameters, which refers to the Decree of the 1986 Ad Hoc Sea Water Intrusion (PAHIAA) Committee [3]. There are 5 qualities of groundwater, namely fresh, rather brackish, brackish, salty, and brine. Analysis of the data used was based on the values of electrical conductivity (EC), total dissolved solids (TDS), and chloride (Cl^-).

Table 2 Intruding distance from the coastline

Parameter	Intruding Distance (km)
TDS	6.52
EC	6.52
Cl^-	7.22

Seawater intrusion in Pekalongan coastal area had intruded to land as far as 6.52 km for TDS and EC parameters. Meanwhile, the farthest distance of 7.22 km was obtained for seawater intrusion, which was reviewed based on the level of salinity (Cl^-). The direction of the dispersion of seawater intrusion from the three parameters was to the south away from the coast. The seawater content which was found at that distance was caused by the phenomenon of sea level rise as tidal floods that inundated that region. Maps of seawater intrusion dispersion were shown in Fig. 14 to 16 based on total dissolved solid, electrical conductivity, and chloride parameters.

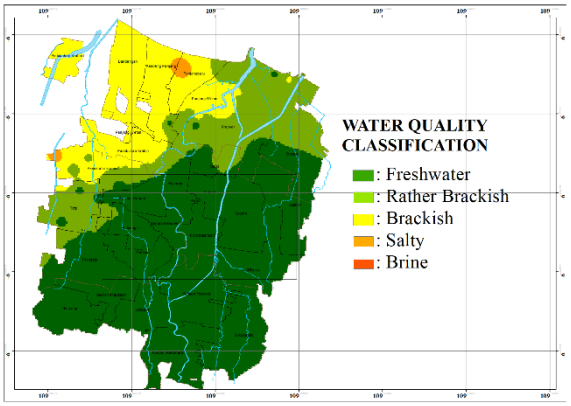

Fig. 14 Dispersion map of seawater intrusion based on TDS parameter.

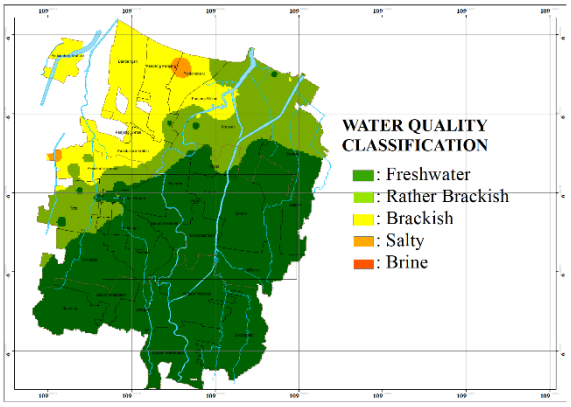

Fig. 15 Dispersion map of seawater intrusion based on EC parameter.

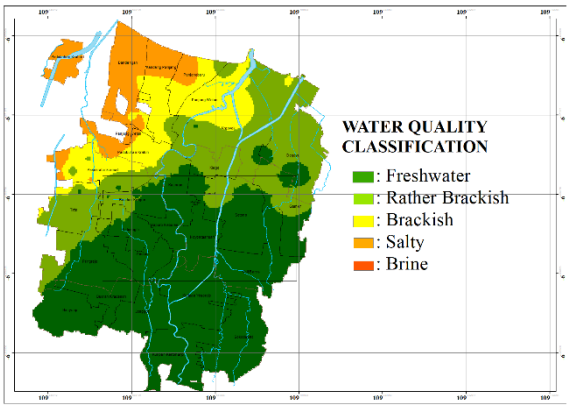

Fig. 16 Dispersion map of seawater intrusion based on Cl^- parameter.

The furthest location affected by seawater intrusion is in Pringrejo Village, West Pekalongan District. The tide was carried by the Bremi River and the Tirto River which directly emptied into the sea. The area passed by the flow of the two rivers mostly had rather brackish to salty water quality.

Based on the analysis of seawater intrusion dispersion in Pekalongan coastal area, the freshwater zone in Pekalongan was still 28.588 km^2 for TDS parameters and 28.357 km^2 for EC parameters. In addition, the area belonging to the freshwater zone was based on Cl^-parameters of 23.945 km^2. So based on the average of the three parameters, South Pekalongan District had the highest average with a region of 100% of its freshwater zone, East Pekalongan District at 86.97%, and West and North Pekalongan District at 57.23% and 8.59%

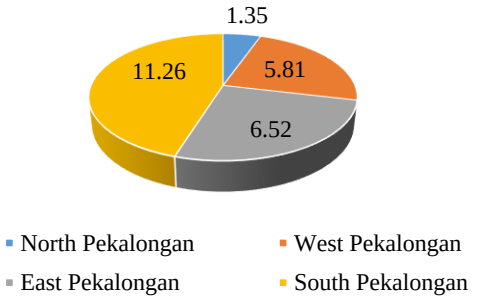

Fig. 17 Diagram of average availability of freshwater zone (km^2) in Pekalongan coastal area.

Based on the results of analysis and mapping, the villages in North Pekalongan District which still had a freshwater zone was a small portion of the southern part of Degayu Village and the southern part of Krapyak with a total area of 1.35 km^2. Whereas all other villages in North Pekalongan District which included Padukuhan Kraton, Bandengan, Kandang Panjang, Panjangbaru, Panjang Wetan, Krapyak, and Degayu villages had been exposed to seawater intrusion with a rather brackish water quality to salty. The study in 2019 was still in accordance with the research conducted in 2013 that in the coastal area of North Pekalongan District, fresh groundwater with EC <650 µmhos / cm was found in the south with the northern boundary through Dukuh, Krapyak Kidul to Degayu section South. For rather brackish groundwater with EC between 600 µmhos/cm - 1,500 µmhos cm found in the middle, including Kandang Panjang Village, Panjang Wetan, Krapyak Lor, and partially Degayu village. Whereas for brackish groundwater with EC > 1,500 µmhos / cm found in the north, covering Bandengan, Panjang Wetan, Kandang Panjang, Panjangbaru, and Degayu village [8]. So that in this case, in a period of 4 years, the availability of freshwater in Padukuhan Kraton Village is not available which indicated a decrease in groundwater quality in the Padukuhan Kraton Village due to infiltration of seawater through tidal floods or sea tides.

Analysis of Shallow Groundwater Quality Decreasing (Unconfined Aquifer)

Specific water quality requirements are theoretically determined by a number of parameters that are specific to a certain range of levels. Above these levels generally, tend to be indicative of contamination or to the level of water pollution or even environmental damage. The level of damage to groundwater conditions and environment can be determined by analysis of groundwater quality based on the parameters of electrical conductivity (EC) and total dissolved solids (TDS). Electrical conductivity (EC) or conductivity is a numerical representation of the ability of water to conduct electric current. The value depends on the content of the dissolved salt, which can be ionized in the water at the temperature when the measurement is made.

Table 3 Decreasing rate classification of confined and unconfined groundwater [9]

Classification Zone	EC (µmhos/cm)	TDS (mg/L)
Safety	< 1,000	< 1,000
Vulnerable	1,000-1,500	1,000-10,000
Critical	1,500-5,000	10,000-100,000
Damaged	> 5,000	>100,000

Based on the value of EC concentration obtained also categorized the level of decline in groundwater quality into 4 zones (safe, vulnerable, critical, and damaged) based on Minister of Energy and Mineral Resources ESDM Number 1451.K / 10 / MEM / 2000. From the results of the analysis with the IDW method in ArcGIS, the quality of groundwater in Pekalongan City which was still in a safe zone is

23.324 km^2, the vulnerable zone was 4.675 km^2, the critical zone was 9.879 km^2, and the damaged zone was 9.094 km^2.

Then, the dispersion map of declining groundwater quality due to seawater intrusion was presented in Fig. 18.

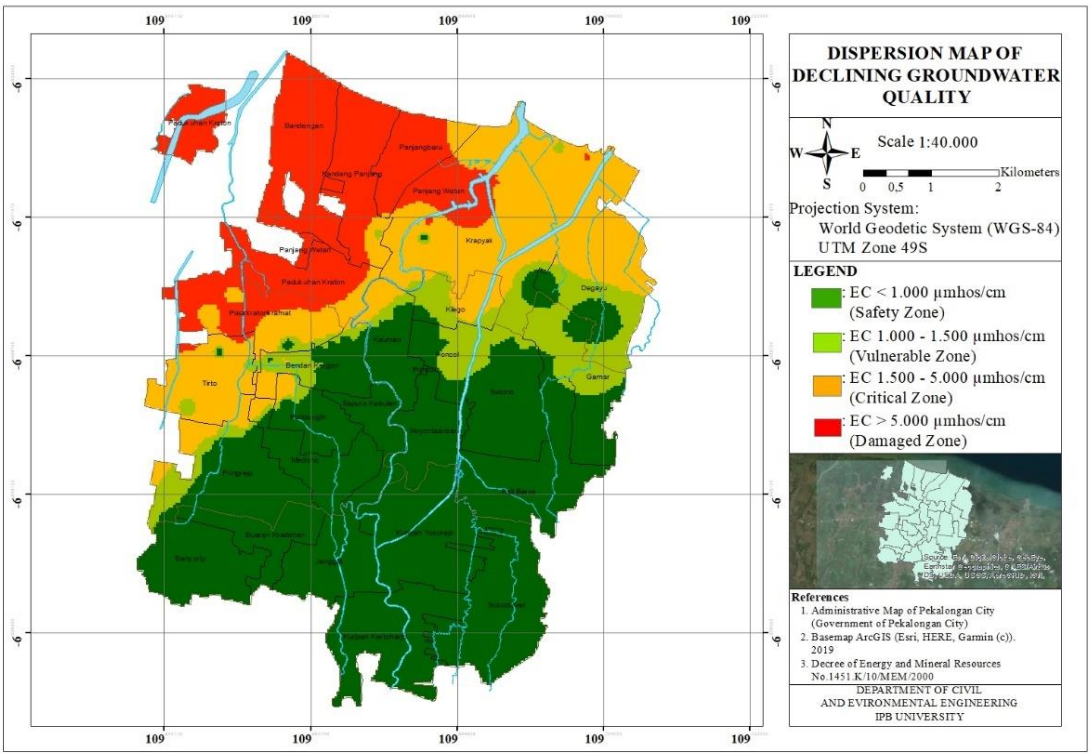

Fig. 18 Dispersion map of declining groundwater quality

The results of the analysis of the decrease in shallow groundwater quality were presented in Table 4 to 7.

Table 4 Dispersion of groundwater quality in West Pekalongan District

Village	Classification Zone
Sapuro Kebulen	Safety
Bendan Kergon	Safety-critical
Pasirkratonkramat	Critical-damaged
Medono	Safety-critical
Podosugih	Safety-critical
Pringrejo	Safety-critical
Tirto	Critical-Damaged

Table 5 Dispersion of groundwater quality in South Pekalongan District

Village	Classification Zone
Kuripan Yosorejo	Safety
Banyurip	Safety
Buaran Kradenan	Safety
Sokoduwet	Safety
Jenggot	Safety
Kuripan Kertoharjo	Safety
Kuripan Yosorejo	Safety

Table 6 Dispersion of groundwater quality in North Pekalongan District

Village	Classification Zone
Krapyak	Safety-damaged
Panjangbaru	Safety-critical
Bandengan	Damaged
Degayu	Safety-critical
Padukuhan Kraton	Critical-damaged
Kandang Panjang	Vulnerable-damaged
Panjang Wetan	Critical-damaged
Setono	Safety-vulnerable
Gamer	Safety-vulnerable

Table 7 Dispersion of groundwater quality in the East Pekalongan District

Village	Classification Zone
Kauman	Safety-critical
Klego	Safety-critical
Noyontaansari	Safety
Poncol	Safety-critical
Kali Baros	Safety

Based on classification zone of declining groundwater quality in Pekalongan coastal area,

South Pekalongan District still had a good groundwater quality because this district didn't have tidal flood area. East Pekalongan District was also dominated by village/subdistrict which had safety classification zone. But, West and North Pekalongan Districts were dominated between critical to damaged zone classification of declining groundwater quality. The type of saline water was usually dominated by sodium and chloride [10]. Other than cations and anions, organics are also associated with TDS but only in small quantities [10].

CONCLUSIONS

Area of Pekalongan coastal area was 46.972 km^2. Seawater intrusion in this region had affected the quality of groundwater which had intruded into 6.52 km from the coast for TDS and EC parameters, and 7.22 km from the coast had been affected by seawater intrusion based on Cl^- parameters. The intruding of seawater was not only affected by the use of continuous shallow wells but more due to the phenomenon of sea tides through tidal flooding carried by the Bremi and Tirto rivers, causing a decrease in the quality of groundwater. The safety zone for decreasing the quality of the groundwater or that was still suitable for use was 23.324 km^2 or about 50% including Banyurip Village, Buaran Kradenan, Jenggot, Kuripan Kertoharjo, Sokoduwet, Kuripan Yosorejo, Baros River, Noyontaansari, Sapuro Kebulen, part of Pringrejo Subdistrict, Medono, Podosugih, Bendan Kergon, Kauman, Poncol, Setono, and Gamer. Whereas, due to seawater intrusion, 9.094 km^2 or 19% of Pekalongan City's territory had been categorized into a damaged zone of shallow or unconfined groundwater.

The relationship between TDS, EC, and Cl^- was not always linear. This situation highly depended on water salinity and material contents. The higher the salinity level or material contents, the more complex mathematical equations were needed in describing those parameters.

BIMODAL NUCLEAR THERMAL PROPULSION FOR INTERPLANETARY EXPLORATION

Elia D'Ambrosi[1] and Sam M Dakka[2]
[1,2] Department of Mechanical, Materials and Manufacturing Engineering, University of Nottingham, UK.

ABSTRACT

Interplanetary exploration is not only a proven recipe for advancement in science and technology; it is also a realistic and profitable goal for long-term human survival. However, current state-of-the-art Chemical Propulsion (CP) systems are inadequate for our future interplanetary objectives. In fact, a combination of low specific impulse and low efficiency lead to narrower launch windows, longer flights, and higher exposure to radiation.

The aim of this study is to make the case for Bimodal Nuclear Thermal Propulsion (BNTP) as the best alternative to today's rocket technologies for a manned mission to Mars. BNTP is a combination of Nuclear-Thermal-Propulsion (NTP) rockets and Nuclear-Electric-Propulsion (NEP) thrusters. The former generates high thrust, the latter high specific impulse; combined, they ensure both high payloads and short transit-times.

The split/sprint mission architecture is outlined as follows: the spacecraft with six astronauts departs in the June 2033 launch window with a fast-conjunction trajectory. The Pewee-class NTP engines provide the initial thrust for escaping Earth and for the propulsive capture at Mars, while the auxiliary NEP ion thrusters deliver constant acceleration during the transfer. The nuclear reactor is used as a power source for the entire spacecraft. This study shows that, using BNTP, the transit time could be reduced from the 260 days of a conventional Hohmann transfer to approximately 80 days, with a total outbound ΔV budget of 11.57 km/s and a spacecraft Initial Mass in Low Earth Orbit (IMLEO) of 250.27t.

Keywords: Mars exploration, Nuclear propulsion, Manned space mission, Orbital mechanics

INTRODUCTION

Problem Identification

It is likely that the next decades will see the development of ambitious space projects, not least in the context of interplanetary exploration. For this reason, it is important to investigate and analyze the different technologies that can enable deep space exploration.

Among these technologies comes propulsion: because of a combination of low specific impulse and low efficiency, current CP systems are insufficient for our future interplanetary objectives. Long transit times pose substantial risks to crews traveling to destinations such as Mars, due to the presence of Solar Radiation (SR) and Galactic-Cosmic Radiation (GCR). Physiological issues, such as bone and vision degradation, muscular atrophy and destruction of the circadian rhythm, combine with psychological problems such as claustrophobia and depression due to confinement. The only alternative to mitigate those effects, without sacrificing the scientific return of a manned mission, is by traveling faster.

Aims and Objectives

The aim of this project is to make the case for Bimodal Nuclear Thermal Propulsion (BNTP) as the best alternative to today's rocket technologies.
The first objective is to examine BNTP technology, presents its characteristics, and outline its benefits by defining key performance parameters.
The second objective is to include BNTP in the design of a preliminary mission architecture for the manned exploration of Mars.

NOMENCLATURE

Table 1 Nomenclature

BNTP	Bimodal Nuclear Thermal Propulsion
CP	Chemical Propulsion
ERV	Earth Re-entry Vehicle
GCR	Galactic Cosmic Radiation
IMLEO	Initial Mass in Low Earth Orbit
ISRU	In-Situ Resource Utilization
LEO	Low Earth Orbit
LH_2	Liquid Hydrogen
MOC	Mars Orbital Capture
NERVA	Nuclear Engine for Rocket Vehicle Applications
NTP	Nuclear Thermal Propulsion
SR	Solar Radiation
TMI	Trans-Mars Injection
Xe	Xenon

METHODOLOGY

Following an analytical methodology, this study examines how to exploit BNTP to decrease transit time and maximize the spaceship operational capability for a crewed mission to Mars.

The first section is descriptive: after defining key parameters for rocket propulsion, it presents the working principles for NTP rockets, NEP thrusters, and for BNTP using a combination of both.

The second section is based on estimation and analytical modelling. First, the transit time and minimum ΔV budget of the mission are calculated based on a Hohmann transfer. After that, a different trajectory is proposed, where NTP generates the high thrust of the planet-centric maneuvers, and NEP provides the high specific impulse necessary during heliocentric transfer. The ΔV budget for the new trajectory is estimated, and the NTP and NEP system are in turn sized to meet the requirements using Tsiolkovsky rocket equation. The total mass budget and the new transit time are thus linearly calculated.

TECHNOLOGY OUTLINE

Figures of Merit

Three figures of merit for space propulsion are established to evaluate the suitability of different propulsion systems, namely the specific impulse I_{sp}, the specific mass α, and the thrust-to-weight ratio.

The specific impulse I_{sp} [s] is a measure of the total impulse delivered by the engine per unit weight of propellant consumed. It measures how effectively the propellant is being used: a rocket with higher I_{sp} needs less propellant for a given mission.

The specific mass α [kg/kW] is the constant of proportionality between the engine system mass and the power delivered to the engine [1]; it measures the mass of the engine system for every kW produced.

Thrust-to-weight ratio is the ratio between the thrust F [N] delivered by the engine and the weight of the engine system [N]; it controls travel time.

When compared between each other, NTP has higher thrust-to-weight ratio and lower α but is limited by a lower I_{sp}. On the contrary, NEP has a very high I_{sp} but suffers from a low thrust-to-weight ratio and a higher α. In addition, burn time t_b for NTP is measured in minutes; for NEP in months or years. Hence the need for BNTP: a propulsion system that combines the best parameters of the two.

Nuclear Thermal Propulsion (NTP)

NTP working principles and components

NTP working principle is the following: hydrogen propellant is directly heated by a nuclear fission power source and then expanded out a nozzle, creating a thrusting force on the rocket. During operation, hydrogen (H_2) propellant is pumped through coolant channels where it is superheated to high temperatures and then expanded out a supersonic nozzle to generate high thrust at more than twice the specific impulse of today's best chemical rockets.

Advantages and disadvantages of NTP

NTP has always been an attractive space propulsion option for several reasons:

- The high I_{sp} reduces the in-orbit total mass for high ΔV missions.
- High F translates into more reasonable interplanetary trip times.
- Since NTP can utilize any gaseous propellant, it has the best potential for using in situ planetary propellant resources [1].
- It requires no large technology scale-up: the smallest tested *Pewee Engine* is adequate if used in a clustered arrangement [2].

However, NTP technology faces some technical issues with increased weight due to the thermal and radiation-shielding requirements [1]. Moreover, the high temperature desirable to maximize the thermodynamic efficiency is limited in a solid core reactor by the materials' thermal limits. Finally, radiation contamination in the case of uncontrolled explosion of the rocket shall be considered, and the reactor shall not become operational until it has been boosted into an orbit well away from Earth surface [6].

Nuclear Electric Propulsion (NEP)

NEP working principles and components

NEP working principle is outlined: heat coming from the reactor core is transferred by a working fluid to a power conversion unit. The electricity is then conditioned to the voltage and current needed and applied to the electric thrusters. Thrust is generated by flowing propellant along with electrical power through the thrusters.

Electrostatic propulsion is currently the only variant of electric propulsion that can enable long-term deep space missions [1].

The most popular and advanced means of electrostatic propulsion are ion thrusters. Molecules of the propellant are first ionized, and then accelerated by Coulomb body force driven by the electrostatic field. A neutralizer emits electrons to counterbalance the accelerated ions' charge.

Advantages and disadvantages of NEP

The reason for NEP popularity is based on some robust advantages:

- It has large mass carrying capabilities, coming from its high I_{sp}.
- Because of the high exhaust velocity of ion engines, less propellant is needed [3].
- The long burn time t_b is essential to provide constant acceleration for deep space exploration missions lasting months or years.
- The EU and the USA have extensive know-how in ion thrusters' technology.

However, the low thrust means that significant spacecraft acceleration requires either engine-on time comparable to the entire mission duration, or that tens or hundreds of individual modules must be used in a clustered arrangement, with a corresponding demand of electric power [4]. Another drawback of NEP is the dumping via a high-area space radiator, which can grow massive and increase the overall mass budget.

Bimodal Nuclear Thermal Propulsion (BNTP)

Overall, NEP is feasible for heavy-payloads propellant-efficient missions with a constant but slow acceleration, but a long mission duration is inevitable. On the other hand, NTP can ensure shorter trip times and more agility at the price of increased weight.

The best rocket propulsion system for deep space is a hybrid, dual-mode NTP-NEP system, the components of which are shown if Fig. 1. NTP would deliver the initial impulsive high thrust to reach escape speed quickly, and the balance between NTP and NEP during the mission trajectory would be optimized based on transit time and propellant.

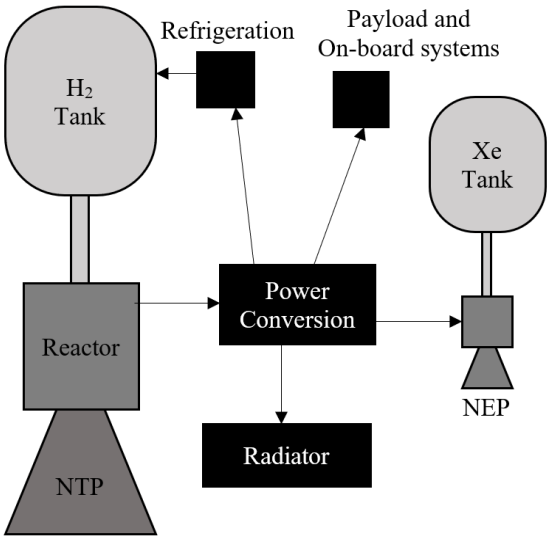

Fig. 1 BNTP components schematic

By reconfiguring the nuclear reactor for bimodal operation, abundant electrical power can be generated to support spacecraft environmental systems, high data rate communications, and an active refrigeration system for long term LH_2 storage [5]. The reactor could also be employed for in-situ operations, avoiding the need to deploy large photovoltaic arrays. Furthermore, using a nuclear reactor as power source for other propulsive methods appears to be the only possibility for powers at the hundreds of kW level.

Standard conversion is based on closed thermal cycles (e.g., Brayton) producing mechanical power driving alternators or dynamos. This technology is now mature in the MW power range, with a feasible conversion efficiency of ~25% [4].

MISSION ARCHITECTURE

The proposed architecture is a split/sprint mission with three spaceships. Two cargo ships pre-deploy the in-situ resource utilization (ISRU) equipment, the habitable module and the Earth Re-entry Vehicle (ERV). The manned spacecraft with six astronauts departs in the June 2033 launch window, uses a fast-conjunction trajectory, and performs a propulsive capture at Mars. It comprises BNTP with three 110kN Pewee-class NTP rockets and a cluster of nine NEP Radio-Frequency Ion Thrusters (RFIT-45).

Ground Rules and Assumptions

The reference NTP system is found in NASA DRA 5.0: a Pewee-class engine with expander cycle capable of $F = 110kN$, $I_{sp} = 900s$ and thrust-to-weight ratio of $F/W = 3.5$ [7]. For the NEP system, the parameters correspond to the RFIT-45 ion thruster, under development since 2010 at the Keldysh Research centre in Moscow [8]. A single RFIT-45 requires a power input of $P_e = 50kW$ and produces an $I_{sp} = 6880s$ at $F = 1.083N$.

Trajectory

To calculate the ΔV budget of the mission, it is first necessary to decide the spacecraft's trajectory. Figure 2 shows the difference between a fast-conjunction class trajectory and its alternative, an opposition class trajectory. Fast-conjunction is preferable because it provides adequate time at Mars for the crew to explore and sample the planet's rich geological diversity while reducing the transit time to and from Mars. In addition, an opposition class trajectory would require a higher ΔV, affecting the propellant mass and increasing the IMLEO.

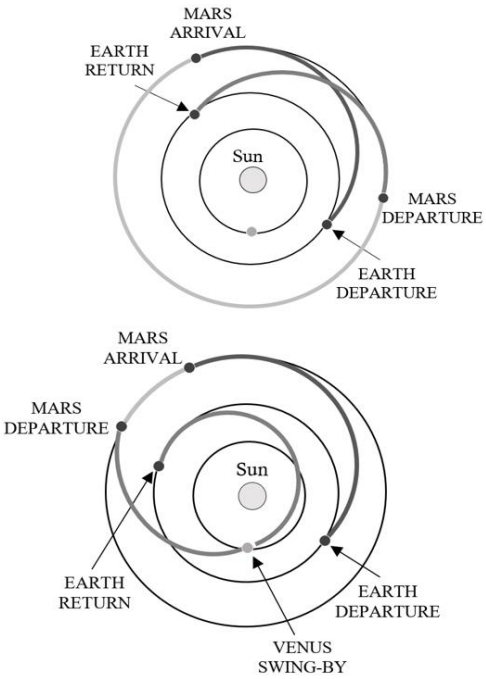

Fig. 2 Fast-conjunction class (top) vs Opposition class (bottom) trajectories

The smallest possible ΔV budget corresponds to a Hohmann transfer manoeuvre, where the spacecraft moves from one circular orbit to another coplanar circular orbit via an elliptical transfer orbit. This manoeuvre is energetically optimized and is therefore the most fuel-efficient. It consists in two impulsive burns: Trans-Mars Injection (TMI) and Mars Orbital Capture (MOC). ΔV_{TMI} indicates the velocity increment required to go from the spacecraft's parking orbit around Earth onto the hyperbolic departure trajectory to Mars. ΔV_{MOC} indicates the velocity change necessary to approach Mars parking orbit velocity from the hyperbolic arrival trajectory.

Assuming the two planets have circular orbits and are coplanar, and that arrival at Mars corresponds to an angle of 180° between the two planets, the ΔV budget for a Hohmann transfer can be calculated.

First, the initial impulsive burn is computed:

$$\Delta V_{TMI} = v_E \cdot \left(\sqrt{(1+e)} - 1\right) \qquad (1.1)$$

Where: $v_E = \sqrt{\mu_s / r_E}$ is the velocity of the Earth in a circular orbit around the Sun.
$e = (r_M - r_E)/(r_M + r_E)$ is the eccentricity of the elliptical transfer.
$\mu_s = 1.327 \cdot 10^{20}\ m^3/s^2$ is the Sun's gravitational parameter.
$r_E = 150 \cdot 10^9 m$ is Earth's orbital radius.
$r_M = 228 \cdot 10^9 m$ is Mars' orbital radius.

Substituting the values yields:

$$\Delta V_{TMI} = 2.94\ km/s \qquad (1.2)$$

Secondly, the final impulsive burn is determined:

$$\Delta V_{MOC} = v_M \cdot \left(1 - \sqrt{(1-e)}\right) \qquad (2.1)$$

Where: $v_M = \sqrt{\mu_s / r_M}$ is the velocity of Mars in a circular orbit around the Sun.

Substituting the values yields:

$$\Delta V_{MOC} = 2.63\ km/s \qquad (2.2)$$

The total ΔV budget for a Hohmann transfer is:

$$\Delta V_{Hohmann} = \Delta V_{TMI} + \Delta V_{MOC} = 5.57\ km/s \qquad (3)$$

Figure 3 displays the Hohmann transfer just described, where "1" is Earth orbit, "3" is Mars orbit, and "2" indicates the transfer trajectory.

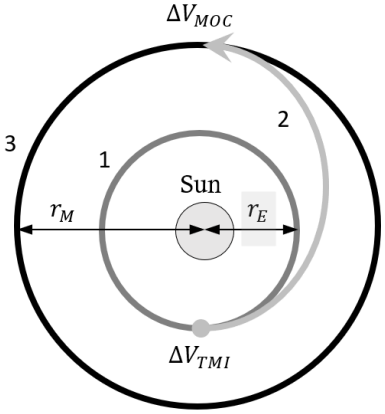

Fig. 3 Earth-Mars Hohmann Transfer

This corresponds to a 1-way transit time of:

$$T = \pi\sqrt{(r_E + r_M)/8\mu_s} = 260\ days \qquad (4)$$

Such transit time is deemed unacceptable for the prolonged risks posed to the crew and the spacecraft, and for the number of contingencies and resources needed during the transfer. This study attempts at finding a compromise between transit time, spacecraft mass and scientific return of the mission, and show how BNTP is a viable propulsion technology for these objectives.

Mars interplanetary transfer by means of BNTP consists of a combination of high- and low-thrust manoeuvres: the high-thrust NTP provides for TMI and MOC, whereas the low-thrust NEP defines the heliocentric transfer. This way, a continuous acceleration is provided, instead of boosting the spacecraft at the start and then coasting all the way to

Mars with the engines off. This concept is illustrated in Fig. 4, where "1" is Earth orbit, "3" is Mars orbit, and "2" indicates the transfer trajectory.

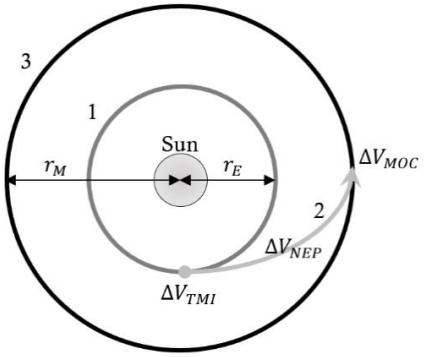

Fig. 4 Earth-Mars Proposed Trajectory

Propulsion Unit

If the spacecraft is constantly accelerating, the ΔV budget of the mission would evidently increase. ΔV_{TMI} and ΔV_{MOC} are kept the same, since TMI and MOC are still performed by NTP, with their sum being $\Delta V_{NTP} = \Delta V_{Hohmann} = 5.57\ km/s$. To account for the constant acceleration imparted by the NEP system, a new $\Delta V_{NEP} = 6km/s$ is added, which is an educated guess and duplicates the total mission ΔV budget. This allows to perform a separate analysis of the engine requirements for NTP and NEP.

Using Tsiolkovsky rocket equation, it is possible to infer the two ratios (R_{NTP} and R_{NEP}) between the spacecraft's wet and dry mass (m_w and m_d).

$$R_{NTP} = NTPm_w/NTPm_d = e^{(\Delta V_{NTP}/(I_{sp}(NTP)\cdot g_E))} = e^{(5770/(900\cdot 9.81))} = 1.922 \quad (5)$$

$$R_{NEP} = NEPm_w/NEPm_d = e^{(\Delta V_{NEP}/(I_{sp}(NEP)\cdot g_E))} = e^{(6000/(6880\cdot 9.81))} = 1.093 \quad (6)$$

The NTP propellant is liquid hydrogen (LH_2) and the corresponding mass is m_{LH2}. For the NEP unit, the propellant is Xenon (Xe) and the corresponding mass is m_{Xe}. The wet mass m_w is the sum of dry mass m_d and propellant mass, hence:

$$R_{NTP} = (NTPm_d + m_{LH2})/NTPm_d \quad (7.1)$$

$$\therefore m_{LH2} = 0.922 \cdot NTPm_d \quad (7.2)$$

$$R_{NEP} = (NEPm_d + m_{Xe})/NEPm_d \quad (8.1)$$

$$\therefore m_{Xe} = 0.093 \cdot NEPm_d \quad (8.2)$$

Mass Budget

Figure 5 illustrates the mass distribution of the spacecraft. The payload is estimated at 50t and includes a crew of six and suits (1.5t), consumables (5.5t), descent stage (4t), aerodescent shell and parachutes (7t), propellant for descent stage (7t) and surface payload (25t). Data for such subsystems is taken and approximated from [5] and reflects a six-astronauts spaceship of similar dimensions.

The LH_2 and Xe propellant masses (m_{LH2} and m_{Xe}) are still to be determined.

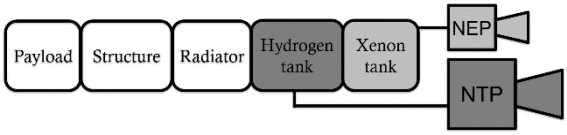

Fig. 5 Structural breakdown

As Borowsky and Dudzinsky explain in [5], other mass must be added, which accounts for the spacecraft's structure: the empty mass of the fuel tanks (14.5t), the Brayton conversion unit (1.5t), the nuclear reactors (18t), the radiation shields (9t), the LH_2 refrigeration system (0.5t), and the avionics (1.5t). Consequently, the total mass of the structure is 45t, and the dry mass $NTPm_d$ becomes:

$$NTPm_d = m_{payload} + m_{structure} + m_{Xe} = 50 + 45 + m_{Xe} = 95 + m_{Xe} \quad (9)$$

It can be noticed that the NEP unit starts operating only once the NTP has performed the TMI. At this point, a good portion of the LH_2 has been consumed, and it would be incorrect to perform the same calculations as in Eq. (9) without taking this into account. Since the ΔV is similar for the two main manoeuvres, it can be assumed that, when the NEP unit comes into operation, the LH_2 tank is half empty.

Therefore, the dry mass $NEPm_d$ becomes:

$$NEPm_d = m_{payload} + m_{structure} + 0.5m_{LH2} = 95 + 0.5m_{LH2} \quad (10)$$

With these figures at hand, the total IMLEO can be computed. Equations (7.2) and (8.2) can be substituted into Eq. (9) and (10) to yield:

$$\frac{m_{LH2}}{0.922} = 95 + m_{Xe} \quad (11)$$

$$\frac{m_{LH2}}{0.093} = 95 + 0.5m_{LH2} \quad (12)$$

This is a two-variables system, and the values of m_{LH2} and m_{Xe} are easily calculated:

$$m_{LH2} = 100.03t \quad (13)$$

$$m_{Xe} = 13.53t \quad (14)$$

These can now be added to the payload and structural masses to give the total IMLEO.

$$IMLEO = m_{payload} + m_{structure} + m_{LH2} + m_{Xe} = 50 + 45 + 100.03 + 13.53 = 208.56t \quad (15)$$

The waste power of the energy converter in the NEP system will have to be radiated to space. To account for the mass of the radiator, the result of equation (18) is multiplied by a factor of 120%.

$$IMLEO = 208.56 \cdot 1.2 = 250.27t \quad (16)$$

Transit Time

Borowsky, McCurdy and Packard [9] indicate that, with a total outbound ΔV of 11.41km/s, a launch in June 2033 could result in a fast conjunction of 80 days. The research in [9] is based on NTP only, and the values for ΔV_{TMI} and ΔV_{MOC} are therefore imprecise. However, since the ΔV budget of the mission proposed here is 11.57km/s, it can be inferred that a similar transit time could be achieved.

This result is a 325% improvement over the Hohmann transit time of 260 days calculated in Eq. (4) and would sensibly reduce the total dosage of hazardous radiation experienced by the crew as well as the total mass of necessary food and water resources.

CONCLUSION

Literature preceding this study has consistently ruled out CP technology for deep-space exploration for its low specific impulse and low efficiency. A tested near-term alternative could come from new propulsive methods powered by nuclear fission.

A descriptive overview has been presented about the technology principles underlying nuclear space propulsion. Relevant parameters have been defined: specific impulse I_{sp}, specific mass α, and thrust-to-weight ratio. In NTP, liquid hydrogen propellant is directly heated by a nuclear reactor and expanded through a nozzle, creating a thrusting force on the rocket. In NEP, electricity generated from the nuclear fission reactor ionizes the molecules of the Xenon propellant and accelerates them out of the thruster by an electrostatic field. When compared between each other, NTP has higher thrust-to-weight ratio and lower specific mass α but is limited by a lower specific impulse I_{sp}, and vice versa. BNTP is a propulsion technology that combines the high thrust of NTP with the high I_{sp} of NEP. In such hybrid mode, NTP could help a Mars spaceship reach escape speed quickly and NEP could operate at high efficiencies for a long duration.

A split/sprint Mars mission with three spaceships has been designed. Two cargo ships pre-deploy the ISRU equipment, the habitable module and the ERV. The manned spacecraft departs in June 2033 launch window with a fast-conjunction trajectory and uses BNTP. It was found that a Hohmann transfer trajectory would result in a ΔV budget of 5.57 km/s and a transfer time of 260 days for the crew. With the bimodal configuration, an auxiliary NEP system could deliver constant acceleration during the transfer, after the impulsive NTP burn. The nuclear reactor could be used as a power source for the spacecraft systems and ISRU, eliminating the need for a large photovoltaic array. The additional NEP ΔV is estimated at 6 km/s, causing the total ΔV budget to become 11.57 km/s and the transit time to be reduced to approximately 80 days. The IMLEO of the manned spacecraft is determined to be 250.27t.

ABSTRACT

The existence of humic substances in peat water impacts on the presence of the dissolved organic matter (DOM) which is the precursor of trihalomethanes (THMs) and haloacetic acids (HAAs). However, information on DOM characteristics, THMs and HAAs Formation Potential (THMFP and HAAFP) in tropical peat water are still limited. This study aimed to determine the correlations between DOM, THMFP, and HAAFP during dry and rainy seasons in tropical peat water in Indonesia. Samples of peat water are taken from the water canal and tidally affected river on Sumatera's peatland during the rainy season and dry season to determine the effects of the seasons and tides. DOM measured by dissolved organic carbon (DOC), specific ultraviolet absorbance and the ratio of UV_{465}/UV_{665} while THMFP determined from a total of THMFP4 measurements and HAAFP determined from measurement of total HAAFP5. Compared to dry season, values of all organic parameters on rainy season were higher but fewer in river. Canal water has a higher DOC while river water has a higher chloride and bromide content. Increasing of DOC in the rainy season correlates with increasing of THMFP4 and HAAFP5. THMFP4 is dominated by chloroform on canal while brominated THMs predominate in river water which correlates with the presence of bromide. Chlorinated HAAs dominate HAAFP5 in canal water while brominated HAAs increases in the river. Seasons and tides affect the appearance of bromide contaminants in water that affects the form of THMFP and HAAFP.

Keywords: Trihalomethanes, Haloacetic acids, Dissolved organic matter, Tropical peat water, Tides and seasons effect

INTRODUCTION

Peat water is colored and acidic and has a nutrient content [1]. Peat water is acidic with a pH <5.2 due to dissolved organic matter (DOM) in the form of humic acid [2]. Humic acid contained in soil and peat water comes from the decomposition of animals and plants from microbial activity. Humic acid is a weak acid that gives brownish color to peat water. The content of organic compounds in peat water depends on the condition of peat soils and the climatic conditions of peat swamps [3]. Peat water is raw water that is not suitable for drinking water. Compared to other better surface water, peat water requires special processing to be used as a source of drinking water.

The composition of DOM in raw water can be different due to land use pattern [4]. The source of organic compounds present in peat water comes from peat soil itself because peatlands are wetlands where the land will be flooded throughout the year so that there are considerable water reserves [5]. Peat soil itself is soil derived from the accumulation of decomposition of plants that are rich in organic matter. Distribution of land or peatland in Indonesia covers all regions in Indonesia. Some of them are in Sumatra, Papua, and Borneo. The peatland which located in each of these regions has different thicknesses [6].

Humic acid is not a hazardous material and has many beneficial environmental effects [7]. However, humic acid is a precursor for the formation of potentially hazardous carcinogen disinfection by-products (DBPs) during the chlorination of water. Besides containing DOM, peat water also contains pathogenic bacteria and halogenated ions (Cl^-, Br^-, F^-, I^-) [8]. The process of chlorine disinfection produces DBPs in the form of THMs and HAAs [9].

The use of chlorine as disinfection has the advantage because the remaining chlorine in water can disinfect introduced pollutants into the water during the storage and distribution process [10]. However, carcinogen disinfection by-products (DBPs) simultaneously generated during the chlorination process including trihalomethanes and haloacetic acids, formed from reactions between chlorine and natural organic matter in water [11,12]. In general, trihalomethane and haloacetic acid concentrations are substantially greater than other By-products [12].

Trihalomethane is a halogenated organic

compound in which three of the four hydrogen methane (CH_4) atoms are replaced by halogen atoms. THM is also a large pollutant that is considered carcinogenic [13]. THM4 (chloroform/TCM, bromodichloromethane/ BDCM, dibromochloro methane/DBCM, and bromoform/TBM) are carcinogens of Cancer Group B (proven to cause cancer in laboratory animals). The United States Environmental Agency (USEPA) established a maximum pollution level of 80 µg/L for total THM4.

The second most important DBPs, haloacetic acids is a carboxylic acid in which halogen atoms replace hydrogen atoms in acetic acid. The United States Environmental Agency (USEPA) sets a maximum pollution level of 60 µg/L of total HAA5 including dichloroacetic acid (DCAA), trichloro-acetic acid (TCAA) monochloroacetic acid (MCAA), monobromoacetic acid (MBAA) and dibromoacetic acid (DBAA), while four other HAAs including tribromoacetic acid (TBAA), bromochloro-acetic acid (BCAA), bromodichloroacetic acid (BDCAA) and chlorodibromoacetic acid (CDBAA) were not included in the regulation [13].

The effect of chloride and bromide ions on THM and HAA formation in the chlorination process was investigated, and it was found that brominated DBP concentrations (Br^-DBP) increased with increasing bromide concentration [14,15]. Experiments show that with increasing bromide concentration, the total THM and HAA results in an increase [16]; The formation of brominated THM and HAA species are increased during chlorination with an increase in bromide concentration [16].

The purpose of this study was to determine the THM and HAA formation potential of peat water based on tidal and seasonal influences that have an impact on the presence of bromide and chloride ions in peat water. As the result of this work, we hope to identify the information on the relationship between tides and seasons in THM and HAA generation characteristics in treatment processes, and finally, to provide suggestions for the control of THM and HAA in water treatment processes.

MATERIAL AND METHOD

Chemicals

A standard mixture of trihalomethanes contain of THM4 (chloroform/TCM, bromodichloromethane /BDCM, dibromochloromethane/DBCM, and bromoform/TBM) in methanol and haloacetic acids containing HAA9 (dichloroacetic acid/DCAA, trichloroacetic acid/TCAA, monochloroacetic acid/MCAA, mono-bromoacetic acid/MBAA, dibromoacetic acid/DBAA, tribromoacetic acid /TBAA), bromochloroacetic acid/BCAA, bromo-dichloroacetic acid/BDCAA and chlorodibromo-acetic acid/CDBAA) in methyl tert-butyl eter (MTBE) were purchased from Sigma Aldrich (USA). GC solvent grade of methyl tert-butyl eter (MTBE), sodium sulfate, sodium bicarbonate, copper II sulfate pentahydrate, sodium sulfite, phosphate buffer, methanol, and sulfuric acid were purchased from Merck (Germany). Chlorine solution (sodium hypochlorite 25%) were purchased from Pudak Scientific (local). All solutions were diluted with mili-Q grade water.

Instrumentations

UV absorbance (UV_{254}, UV_{465}, and UV_{665}) was measured using a UV-Vis Spectrophotometer (Shimadzu UV-1700). TOC Analyzer (Shimadzu TOC VCSH) are used to measure DOC (dissolved organic carbon) using EPA 415.3 method. Bromide was determined with APHA 4500 Br^- B using phenol red colorimetric method. Chloride was determined by APHA 4500 Cl^- B using argentometric method.

Gas Chromatography (GC) Agilent 7890A and Agilent 5975C Mass Selective Detector (MSD) were used to analyze HAA and THM. Agilent 7693 Series Automatic Liquid Sampler is used for sample injection and Agilent MSD ChemStation software is used to process data.

Trihalomethane Analysis

In the THM analysis, 1.0 µl of the sample was entered into GC by splitless injection and completed in the HP-5MS capillary column 30 m × 0.25 mm, 0.25 mm thick. The gas carrier (helium) rises at a constant inlet pressure of 15 kPa with a flow rate of 1.5 ml/minute. The injector temperature is 93 °C. The oven temperature is set to 90 °C, and the setting temperature is set to 300 °C.

Haloacetic acids Analysis

In the HAA analysis, setting GC conditions was carried out based on EPA 552 modified with Xie et al [17] for GC-MS analysis. 40 mL water sample was extracted using 4 mL MTBE after acidified to pH 2 using concentrated sulfuric acid and the addition of 16 g sodium sulfate and 3 g of copper II sulfate pentahydrate. Approximately 3 mL of the organic phase was methylated with acidic methanol in 50 ˚C ±2 for 2 hours. 1.0 µL of the sample was entered into GC by splitless injection and filled in the HP-5MS capillary column thickness 30m × 0.25mm, 0.25mm. The flow rate of the carrier gas (helium) is 1.0 mL/minute (constant flow). The oven temperature is set at 35 ˚C for 10 minutes and then raised to 75 ˚C at a level of 5 ˚C/minute and increased for 15 minutes, then raised to 100 ˚C with 5 ˚C/minute for 5 minutes, 135˚C with rose 5 ˚C/minute for 2 minutes, and 185

˚C by increasing 25˚C/minute for 2 minutes. The injector temperature is 200 ˚C and the line transfer is received at 280 ˚C. MSD is operated in Electron Impact (EI) mode. The ion source temperature is regulated 230 ˚C with electron energy being 70 eV.

Trihalomethane and Haloacetic Acids Formation Potential

The trihalomethane and haloacetic acid formation potential (THMFP and HAAFP) is the quantity of THMs and HAAs formed where the water sample is dosed with excess chlorine for 7 days at 25 °C and pH 7. The chlorine dosage was determined so that the remaining chlorine was 3-5 mg/L after 7 days of incubation. The method was adapted from standard method 5710B procedure [18]. In this method, 97.5 mL samples were dosed with 2 ml 0.5 M phosphate buffer solution to buffer the sample at pH 7 and 0.5 mL NaOCl. The sample was incubated for 7 days in a dark at 25 °C. After 7 days, 0.5 mL of cooling solution (sodium sulfite 10%) was added to prevent further reaction and the sample was cooled until analysis.

Sample Extraction

Trihalomethane extraction

The sample extraction procedure for THM analysis was carried out based on the EPA 551.1 Method [19] with minor modification. 50 mL of sample water was extracted with 3 mL MTBE by adding 20 gr of sodium sulfate anhydrous to increase the strength of the aqueous phase ion. After an organic phase (MTBE) and the water phase were separated, micro pipette used to remove approximately 1µL MTBE to autosampler vial for GC/MS analysis.

Haloacetic acid extraction

The sample extraction procedure for HAA analysis was carried out based on the EPA 552.2 Method. [20]. After adding 1mL of concentrated sulphuric acid, 16gr of sodium sulfate anhydrous, 2gr of copper II sulfate pentahydrate and surrogate (2,3-dibromopropionic acid), 40 mL of water sample was extracted with 4 mL MTBE and added internal standard, 1,2,3-trichloropropane, manual for 2 minutes. 2.5mL of extract was methylated by adding 1.0 mL of 10% sulphuric acid solution in methanol and heated at 50˚C for 2 hours. After neutralization with 4mL of saturated sodium bicarbonate solution, the extract was analyzed using GC/MS.

Samples

Sampling was carried out in Peria River and water canal found in Indragiri Hilir Regency's peatland, Riau Province, Indoneisa to see the effects of tides. Samples were taken in two different places, in the rainy and dry season. River water that affected by tides and canal water that was not affected by tides. the water samples are canal water at dry season (CWD), river water at dry season (RWD), Canal water at rainy season (CWR) and river water at rainy season (RWR). The sampling location shows in Figure 1.

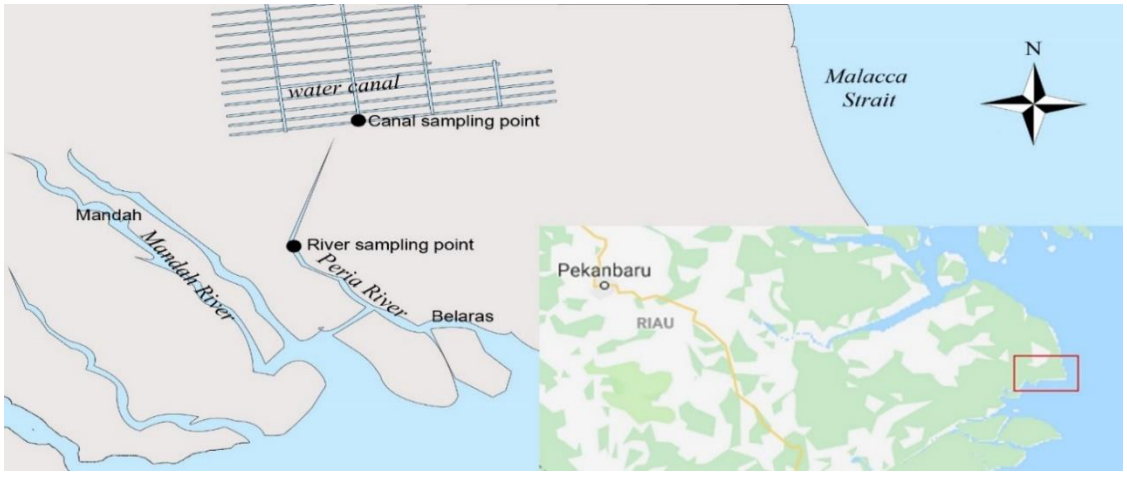

Fig.1 Sampling locations

RESULT AND DISCUSSION

Properties of Peat Water

Table 1 shows that the DOC values are ranging from 22.2 mg.C/L-56.2 mg.C/L where the highest concentration is found in peat water originating from CWR and the lowest comes from RWD. The DOC value corresponds to the UV_{254} absorbance. The highest UV_{254} absorbance was found in canal water during the rainy season which was 3.175/cm and the lowest was in river water during the dry season which

was 1.246/cm. The SUVA values range from 5.5 L/mg.m-5.9 L/mg.m which indicates that the compounds of NOM in peat water consist mostly of humic compounds that have high aromaticity and are strongly hydrophobic. Increasing of DOC in the rainy season can occur due to the leaching process that dissolves NOM from peat soil [21].

The E4/E6 ratio illustrates the presence of high molecular weight NOM in water [22]. The smaller E4/E6 ratio is found in peat water originating CWR, which is 4,914, whereas a large E4/E6 ratio is found in peat water originating from rivers in the dry season (= 8,286). The presence of chloride ions in river greater than canal due to the tidal influence. Bromide ions are only found in river peat water.

Table 1 Properties of peat waters

	CWD	RWD	CWR	RWR
DOC (mg.C/L)	44.46	22.2	56.2	47.4
UV_{254} (1/cm)	2.61	1.24	3.17	2.60
SUVA (L/mg.m)	5.9	5.6	5.6	5.5
E_4/E_6	7.8	8.28	4.91	5.57
Cl^- (mg/L)	94	192	88	200
Br^- (mg/L)	-	175.47	-	100

Trihalomethane Formation Potential

THMFP was determined from the total formation of THM4 after chlorination for seven days due to variations in the dominant compounds formed shows in Fig. 2. THMFP on peat water increase in the rainy season because increasing of DOC [23] during the rainy season due to NOM leaching from peat soil [22]. THMFP in peat water originating from canals dominated by TCM formation. According to Stuart et al. [23], Garrido and Ponseca [24], Panyapinyopol et al. [25], Sururi et al [4] TCM was the largest THM formed during chlorination. TCM concentration in the dry season from 658.27 µg/L in dry season becomes 1024.82 µg/L during the rainy season.

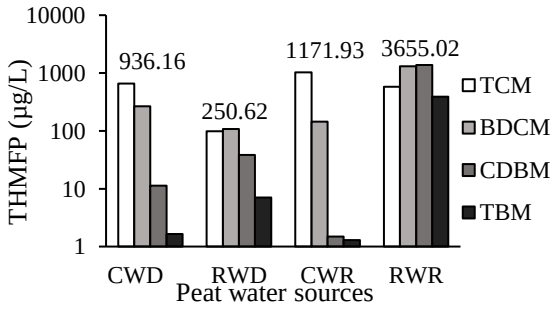

Fig. 2 Trihalomethane formation potential of peat water based on THM4 formation

The total THM4 which was THMFP was also increased in the rainy season from 936.16 µg/L to 1171.93 µg/L. In the river, THMFP is dominated by BDCM and CBDM in accordance with the Rajamohan [26] study. The presence of TBM is a significant difference between canal water and river water where the presence of TBM has a higher concentration in river water. This is in accordance with Marhaba et al [27] and Padhi et al [28] that bromide-containing water produce higher brominated THM. The pattern of THM formation in river water has the same pattern in peat canal water where the concentration of each THM increases during the rainy season. The THMFP increased from 250.65 µg/L to 1171.93 µg/L.

Haloacetic acid Formation Potential

HAAFP was determined from the total formation of HAA5 after chlorination for seven days due to variations in the dominant compounds formed (Fig.3). HAAFP in the canal water is dominated by DCAA and TCAA that corresponds to the results of He et al. [29] which indicate chlorine reactivity with low molecular weight compounds during the disinfection process. The DCAA and TCAA concentrations increased from 3387.50 µg/L and 3329.19 µg/L to 6898.31 µg/L and 5894.21 µg/L during the rainy season.

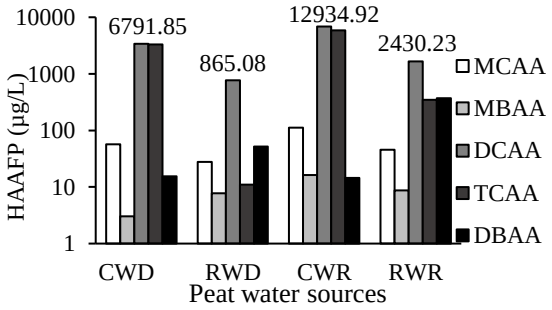

Fig. 3 Haloacetic acid formation potential of peat water based on HAA5 formation

Increased concentrations of DCAA and TCAA resulted in an increase in total HAA5 which was HAAFP from 6791.85 µg/L to 12934.92 µg/L. The same pattern occurs in peat water originating from rivers but HAAFP is only dominated by DCAA. This result corresponds to Yu et al. [30] and Yue et al. [31] where the low concentration of TCAA is influenced by the high concentration of bromide ions originating from the sea, so the presence of TCAA is replaced by bromine-based HAA (DBAA). Total HAAFP in river water increases in the rainy season from 856.08 µg/L to 2430.23 µg/L.

Specifc Formation Potential

Figure 4 shows the Specific Trihalomethane Formation Potential (STHMFP) and Specific

Haloacetic Acid Formation Potential (SHAAFP). Compared with DOC values, STHMFP of peat water ranged from 11.28-77.0 µg/mg.C. There was no big difference in HAAFP on canal water between dry and rainy seasons. On the other hand, STHMFP of river water in the dry season rise significantly compared to the rainy season that related to E4/E6 ratio. The ratio of E4/E6 of river water in the dry season was higher than a rainy season but the DOC value was smaller that relate to the appearance of low molecular weight NOM-THMs precursor.

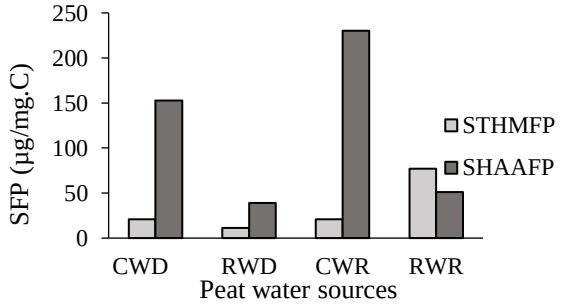

Fig. 4 Specific Trihalomethane and Haloacetic acid formation potential of pat water

SHAAFP of peat water range from 38.96-230.15 µg/mg.C where the highest value is found in canal water during the rainy season and related to higher E4/E6 ratio. This value is not much different from raw water originating from Bangkhan Water Treatment at 288 µg / mg.C [32]. Canal water has a higher E4/E6 ratio indicated that canal water has more humic content that major precursor to HAAs. SHAAFP of river water was raised but has a smaller ratio than canal water indicated that low molecular weight was not a major precursor of HAA compared to humic substances.

CONCLUSIONS

This work is conducted to identify the information on the relationship between tides and seasons in THM and HAA generation characteristics in tropical peat water during the chlorination process. The peat water has high DOC values ranged from 22.2-56.2 mg/L that the highest value found in canal water in the rainy season. THMFP and HAAFP are higher in the canal water and the rainy season. Bromide ion contains in river water influence the formation of brominated THM and HAA during chlorination. THMFP is dominated by TCM in canal water and dominated by BDCM and CBDM in river water. HAAFP in the canal water is dominated by DCAA and TCAA then in river water only dominated by DCAA.

ENHANCED SAFE CONDUCT AND PREPARATION FOR EFFECTIVE EVACUATION (ESCAPEE) USING GAMA

Shaun Manalili[1], Hannah Rafols [2], Joaquin Ramos[3], Syyida Shah[4]
[1] Lessandro Estelito Garciano, De La Salle University, Philippines

ABSTRACT

Hospitals are essential structures with the purpose of providing healthcare and assistance especially during disasters. These facilities are also prone to fire due to the presence of electrical equipment, oxygen tanks, chemicals, and other flammable materials. In an event of a fire, the layout of the hospital must be able to provide an effective evacuation. In this paper, the evacuation of ten emergency rooms (ER) was simulated. The simulation for the rooms utilized an agent-based model (ABM) by using GAMA Platform. Varying densities were simulated per ER and a fire simulation was done. The simulations resulted to total evacuation time for the different ERs and the mortality rate considering a fire inside the room. The results show that the number of occupants affected the evacuation time by 10 to 20 seconds. Considering a minimum evacuation time of 30 seconds, the simulations showed that three hospitals will never evacuate longer than 30 seconds, 3 needed a required density, while 4 would always take longer than 40 seconds. In addition, there is also a weak correlation between the area of the ER and the evacuation time. Based on observation of the simulations, the location of the exits plays a significant role in safe evacuation.

Keywords: Evacuation, Fire, Agent based model, Hospitals, GAMA Platform

INTRODUCTION

A disaster, according to the International Federation of Red Cross and Red Crescent Societies [1], is a sudden phenomenon that disrupts a unit's functionality. Shaluf [2] stated that disasters can be classified into three types: natural, man-made, and hybrid. Among the various disasters, fire alone accounts for 39.2% of the major disasters worldwide [3]. The Philippines are among those countries that have a tragic and significant record of fire incidents that resulted to numerous casualties. Some incidents are the Ozone Disco Fire in 1996 that resulted to a casualty count of 162, the Valenzuela Factory fire in 2015 that resulted to 74 deaths and the fire in NCCC mall in 2017 that resulted to 39 deaths [4].

Almost any building or structure is vulnerable to fire. This study focuses on hospitals, which are essential structures. Its purpose is to provide healthcare, assistance and accommodation during times of disasters. However, hospitals can be very vulnerable to disasters as well, especially to fire. The presence of volatile substances, extremely flammable materials and equipment with high tendency of overheating make hospitals more susceptible to fire. In the event wherein a fire may occur, hospitals must readily have a proper evacuation plan and layout. This may reduce the likelihood of casualties as a result of the fire.

Evacuation is needed when a hazard poses harm to the health and safety of people inside a facility or structure. This must be observed, practiced and executed especially in unforeseen and urgent instances when fire occurs. To preserve life and safety, the occupants of the building need to evacuate by following the building's evacuation plan. Accurate and effective evacuation plans are created and improved based on real-time evacuation drills. In the case of hospitals, it may be difficult to commence. Conducting drills may cause commotion, inconvenience and disruption in operations. In this study, evacuation simulation is used instead. It is an alternative quantitative method to determine evacuation times based on the concepts of crowd dynamics and pedestrian motion. This study uses an agent-based model through the use of GAMA Platform, a simulation software that is capable of modelling explicit multi-agent simulations.

Ten hospital emergency room layouts were obtained in this study. The research includes two phases of evacuation simulations. The first set of simulations involve the evacuation of ten hospital emergency layouts, where graphs of evacuation time versus occupancy density are plotted. The second set of simulations involve the evacuation of three representative layouts for small, medium and large areas. The division of the areas are determined by the researchers based on the obtained layouts. The second

phase of simulations, fire was introduced at random location with a rate ranging from 0.5 m/s to 2.0 m/s.

RELATED LITERATURE

Allowable Unit Area per Occupant

A facility or structure can only occupy a certain density at a time. According to the National Building Code of the Philippines [5], the allowable unit area per occupant of a hospital or sanitaria is 8.4 m^2/person.

Evacuation Models

There are many ways to simulate an evacuation model. Such methods include flow-based models, agent-based model (ABM) and cellular automata (CA). A flow-based model is one that considers a continuous flow movement between evacuees, without the consideration of varying human characteristics and direction [6]. The second type of model is the agent-based model, an improvement of the flow model that already considers a number of factors like the building configuration and the evacuees' proximity between each other. The last type of model is the CA model which utilizes cell grids and some rules of movement to come across this area of grids.

This research utilizes agent-based modeling or ABM. Agent interactions in multiplex systems can be simulated through this type of model. Therefore, several factors among agents and the floor layout can be investigated. Ha and Lykotrafitis [7] investigated the effect of the architectural complexity of a building on the crowd motion while commencing an evacuation. In their study, they explored the effects of the evacuees' panic level by varying desired agent speeds. They also explored the effect of the complexity of the floor plan by varying the door sizes. It was found that as the room door size and the desired speed increase, the evacuation time immediately decreased. The study employed a relationship between the size of the egresses having to match the configuration of the room and the speed of the occupants leaving the room.

Kasereka, Kasoro, Kyamakya, Doungmo Goufo, Chokki, & Yengo [8] used ABM to simulate evacuation of people in the case of fire. They were able to explore different factors and establish relationships between these factors. As the number of evacuees are higher, the fatality increases. As the speed of the agents increased, the number of survivors increased. The ABM model allows integration of different factors that influence the model, opening new doors of possibilities in mimicking real life scenarios. The study utilized GAMA to simulate an evacuation of supermarkets in case of fire and they have concluded that the faster the velocity of the occupants in the buildings, the higher the number of people who have evacuated. In addition, the number of deaths had decreased. Addition of exit doors had significantly influenced the model in such a way where the evacuation time of the occupants had significantly decreased and that the number of survivors had increased.

GAMA Platform

Claridades, Villanueva and Macatulad [9] conducted a simulation of an evacuation using GAMA Platform and they have discovered that several factors regarding human behavior such as original states, panic, eating and studying will hasten the evacuation process while sleeping and going to the bathroom are considered as impedances in the evacuation. Aside from that, the results of the evacuation time suggest that altering the width of the corridor and pathways towards the exit can affect the response time. When the width of the pathways increased, the response time decreased.

Macatulad and Blanco [10] conducted an evacuation simulation of the Melchor Hall building at the Univeristy of the Philippines, Diliman. The researchers have incorporated ABM and GIS to model the evacuation of the people and to look at different scenarios for evacuation planning. Simulating the ABM in GAMA allowed the researchers to construct a 3DGIS-BASED model of the structure. The test simulation in GAMA was satisfactory assuming only 6% room capacity. Considering only the first floor, the researchers discovered that the people at the first floor managed to evacuate at 9 seconds on average while the total evacuation time for the five-storey building is 96 seconds.

MODEL DESCRIPTION

The model works by first dividing the layout of the ER into square grids size 0. 4 m x 0.4 m. An example of the layout being divided into the grids are shown in Fig. 1. The obstructions are determined when they overlap cells. These cells are then obstructions and the agents will not be able to pass through those cells. Agents are also considered to obstacles to other agents, this prevents overlapping of cells.

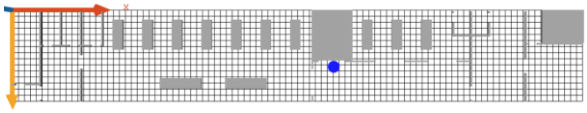

Fig. 1 Sample ER layout divided into square grids

The agents in the model move by utilizing a Moore Neighborhood. This means that an agent can have the option of moving to eight different directions as explained by Brugiere [11]. Figure 2 shows the

illustration of the neighborhood. Given an agent in the center shown as a blue circle, the agent will be able to move into any of the eight directions. The agent will choose the shortest path going towards a selected exit. The only time that there will be less than 8 options is when an obstacle is present in the cell.

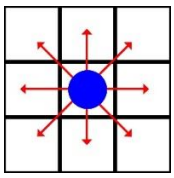

Fig. 2 Agent movement using Moore neighborhood

In choosing the exits, the agents select the closest direct exit. The agents then move towards the exit using the shortest path possible. Once the agent reaches a distance less than or equal to 0.4 m from the location of the exit, they are considered to be safe and have exited the layout. The program records the number of people that have exited at a given time and which exit they used. The independent variables used in the study are occupancy density, velocity of fire, number of people. The dependent variables are evacuation time and casualties. Controlled variables include the ER layout, exit location and fire source.

The research determined the amount of time steps and total time to complete the evacuation for 10 different hospital emergency rooms to acquire the evacuation time. In addition to the 10 hospitals, 3 hospitals were selected to be simulated considering a fire within the room. The controlled variables for each setup were the emergency room layout, with the nonstructural components or obstacles, the locations of the exits, and the source of fire. The independent variables in each experimental setup included the density of the occupants and the rate of spread of fire. Five trials of the simulation were done for each density for 11 varying densities of the ten hospitals. Three trials were simulated considering a fire source for three densities for three different hospitals. In total, 658 simulations were done. In the ABM model the layout of each hospital was considered including the obstructions present such as walls, chairs, beds, tables, and other immovable equipment. In order to simulate the most realistic evacuation simulation possible, factors that contribute to the decision-making of the agents such as distance effects and location of exits were also taken into account. The results of the simulation were the evacuation times with corresponding densities and the number of casualties due to fire. These results were analyzed to assess the efficiency and effectiveness of the evacuation, as well as to evaluate and recommend a solution to improve the plan layout.

DATA AND RESULTS

Prior to simulations, the researchers investigated ten hospital emergency room layouts as shown in Table 2. The smallest of the surveyed hospitals is about 200 m^2 and the largest about 2000 m^2.

Table 2 Areas of the ten surveyed hospitals

Hospital	ER Area (m^2)	Total Floor Area (m^2)
A	212	1,804
B	241	9,206
C	321	10,644
D	382	8,670
E	393	4,806
F	665	18,964
G	959	6,712
H	1,038	6,404
I	1,071	13,851
J	1,820	96,358

Based on the values shown in Table 2, there is a weak correlation between the total floor area and the area of the hospital ER. However, it is evident that the area of the ER ranges from 2% to 16% of the total hospital area.

The evacuation time for the varying densities for all the ten hospitals are shown in Fig. 3 and Fig. 4. The hospitals named alphabetically are in increasing order. Hospital A has the least ER area while hospital J has the largest area. It was found that the minimum and maximum evacuation time considering the different densities are shown in Table 3. The change in density effected the evacuation time by about 7 – 20 seconds.

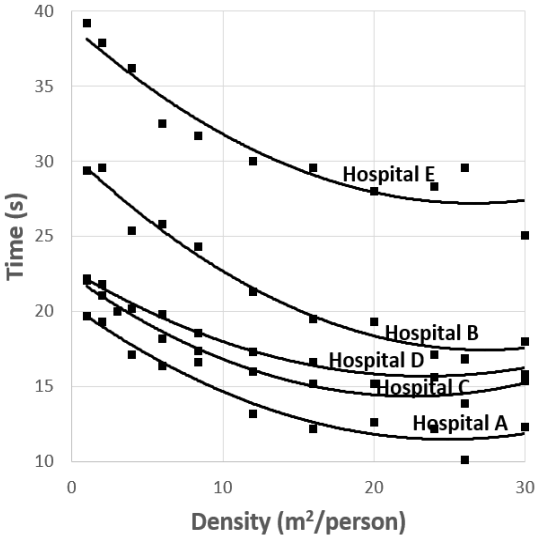

Fig. 3 Density versus time graph for Hospitals A-E

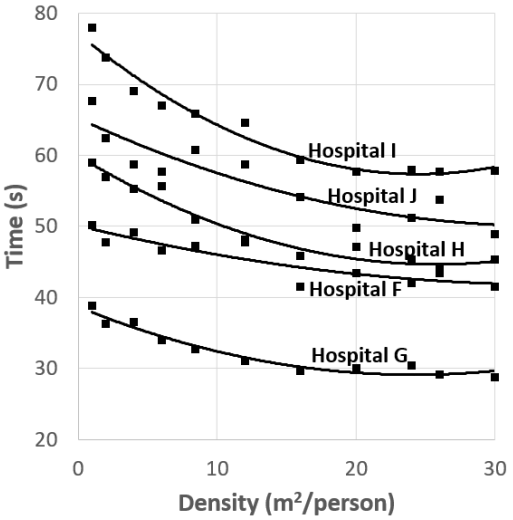

Fig. 4 Density versus time graph for Hospitals F-J

Table 3 Minimum and maximum evacuation times

Hospital	No. of Exits	Minimum Evac Time (s)	Maximum Evac Time (s)
A	2	10.1	19.7
B	1	18	29.6
C	2	15.4	22.2
D	2	15.2	22.1
E	1	25.1	39.2
F	2	50.2	41.5
G	3	28.8	38.9
H	2	45.3	59
I	2	57.8	78
J	3	48.9	67.7

The graph of the area of the ten hospitals versus the evacuation time for three different densities are shown in Fig. 5. the best fit polynomial curve for a high, medium, and low densities using the estimated area from all ten emergency room layouts. It can be observed that the area of the hospital has an effect on the evacuation time, however, there are some points where the evacuation of one room can be faster than that of a smaller room due to other factors such as the locations of the exits and the layout itself which includes the walls and obstacles. The number of exits ranged from one exit to three exits and it was found that there was no correlation with the number of exits.

Fire hazards were simulated by assuming it to start as a circle in the agent-based model with a diameter of 0.4 m. The hazard then continued to expand given varying velocities and the casualties and mortality rates were acquired for Hospital B, G, and J which were determined as the representative areas for small, medium and large areas for the ten hospitals gathered.

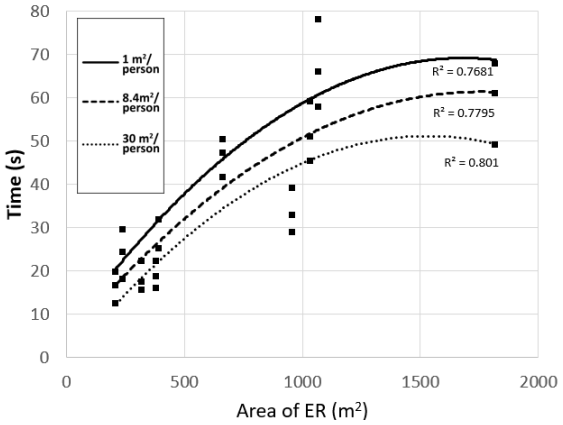

Fig. 5 Effect of ER area on evacuation time

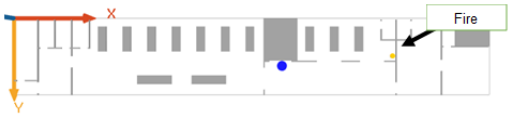

Fig. 6 ER Layout of Hospital B and the fire source

Figure 6 shows the layout of Hospital B and where the fire was assumed to start. The resulting graph of the mortality rate for varying velocities of the hazard is plotted in Fig. 7. The starting location of fire is placed near the oxygen tanks. Upon simulating, the curves produced by introducing fire to the layout of hospital B were steep. This may be due to the single exit located at the center of the layout. As the fire increases in diameter, it slowly spreads towards the exit. Therefore, agents who are travelling from the right side of the layout when engulfed by the growing radius of the fire, were already considered to be casualties. The maximum mortality rate of hospital B ranges from 80% to 90%.

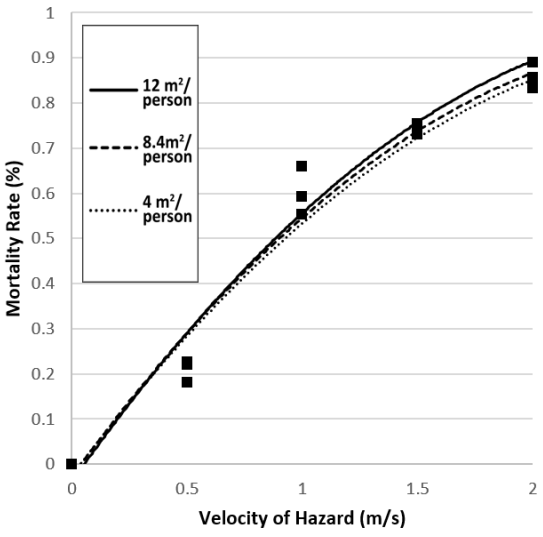

Fig. 7 Velocity of Hazard vs. Mortality Rate of Hospital

Figure 8 shows the layout of hospital G. It is evident that hospital G has a larger area and has more exits as compared to hospital B. The starting location of the fire is assigned at the equipment room of the layout where fire will most likely to occur.

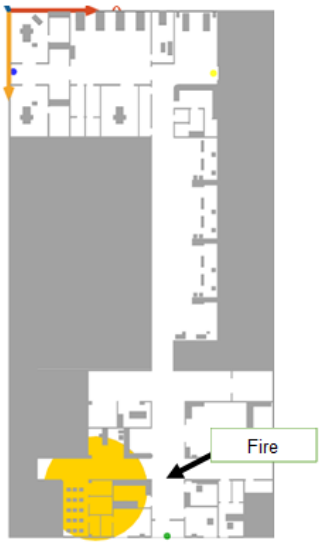

Fig. 8 ER Layout of Hospital G and the source of fire

The graph of the velocity of fire versus the mortality rate of hospital G shown in Fig. 9. The graph produced flatter slopes compared to the curves produced for hospital B. This implies that hospital G's layout is effective since it produced a flatter slope for the curves showing the relationship of the rate of fire with respect to the mortality rate. The highest speed of fire which is 2 m/s produced a smaller mortality rate for Hospital G as compared to Hospital B. Some of the factors that have contributed to the results are the location and number of exits as well as the presence of obstructions near the exits.

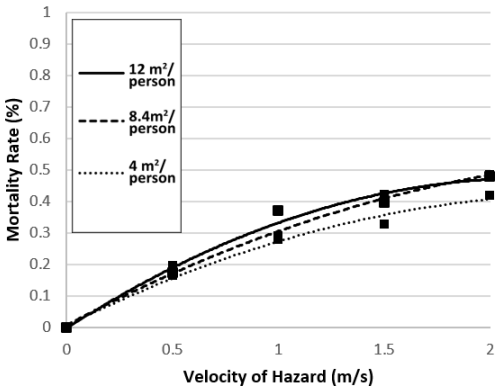

Fig. 9 Velocity of Hazard vs. Mortality Rate (Hospital G)

Figure 10 shows the layout of Hospital J and where the fire was assumed to start. The resulting graph of the mortality rate for varying velocities of the hazard is plotted in Fig. 11. Hospital J has the largest area among the ten hospitals. Fire was introduced in the simulation and was placed near the third exit. Over time, the fire spreads towards the exit, engulfing the area and the agents that chose that specific exit.

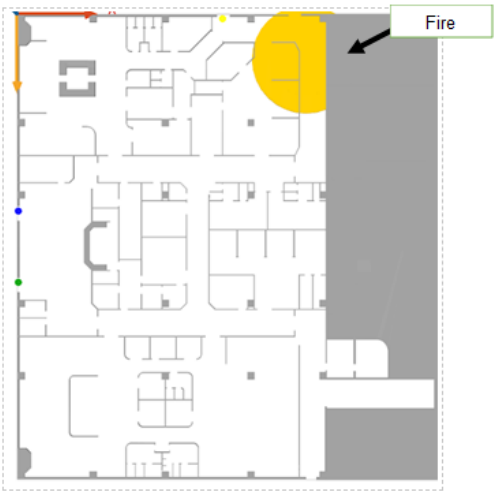

Fig. 10 ER Layout of Hospital J and the source of fire

The graph of Hospital J, as shown in Fig. 11, shows curves that are slightly steeper than hospital G but flatter than hospital B. The implication of this is although fire was initially near the exit, the highest velocity of fire produced a smaller mortality rate as compared to hospital B. The maximum mortality rate of hospital J ranges from values of approximately 58% to 72% took the exit at the rear side of the layout. Its distinct features include three exits: one at the top and two on the side as shown in Fig. 10.

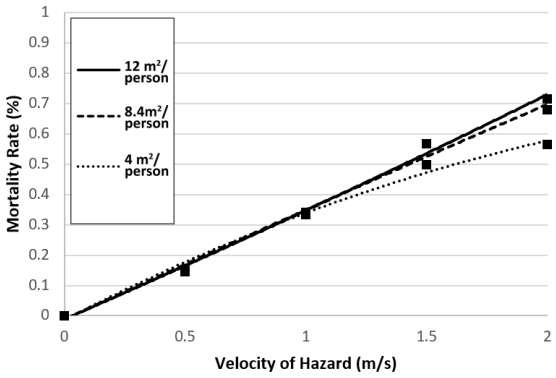

Fig. 11 Velocity of Hazard vs. Mortality Rate (Hospital J)

CONCLUSION

Ten emergency rooms were simulated for the evacuation time and fire. The researchers were able to

develop an ABM program to simulate the evacuation. Varying the densities of the room effected the time by 10 to 20 seconds, which were graphed. Moreover, it was found that although the area of the hospital has a weak correlation with time, it still has an effect on the evacuation time. Evacuation time becomes faster when the exits are more spread out from one another, and serve equal number of occupants. The mortality rate is also based on how fast the fire is, where the fire source is, and locations of the exits. Having more alternative routes lessens the mortality rate.

ACKNOWLEDGEMENTS

The researchers would like to extend their sincerest gratitude to their thesis adviser for helping them in analyzing and interpreting the data. In addition to their thesis adviser, their heartfelt gratitude extends to the Structural Engineering Division and to the Civil Engineering Department for providing them insightful ideas to improve their study. Lastly, the researchers wish to acknowledge their institution, De La Salle University, for the opportunity to conduct their study.

GREEN BUSINESS MODEL OF BIOMASS VERY SMALL POWER PRODUCERS IN THAILAND

Paron Vongchan[1], Chutarat Chompunth[2] and Wisakha Phoochinda[3]
[1] Graduate School of Environmental Development Administration, National Institute of Development Administration, Thailand

ABSTRACT

Thailand has traditionally been an agricultural economy which is appropriate for biomass energy because electricity can be produced from agricultural waste in large quantity. However, without proper management, electricity production from biomass, specifically biomass very small power plants located in communities across the country, may cause pollution and health threats impacting the environment, public health, and conflict from the pollution-affected communities around the biomass power plants. This research aimed to construct Green Business Model for electricity production using biomass for Biomass Very Small Power Producers in Thailand by applying the Sustainability Balanced Scorecard and to evaluate the model by interviewing experts and stakeholders of biomass electricity production. The study showed that the concept of green business model of Biomass Very Small Power Producers consisted of four key aspects namely 1) Stakeholders perspective including business entrepreneurs, feedstock producers/suppliers, feedstock transport operators, community, government, and non-governmental organizations 2) Sustainability management perspective including economic management, social management, and environmental management 3) Effectiveness perspective including Social Return on Investment and 4) Learning & growth perspective including training/learning and innovation/technology. Biomass Very Small Power Producers could deploy the concept of this model to generate profit coupled with responsibility for the environment and society. As a consequence, the green business model of Biomass Very Small Power Producers could benefit the agricultural and community sectors such as energy security, reduction of energy import, support of agricultural waste management, local occupation in community, and revenue generation within communities from agricultural waste. It would lead to sustainable development and benefit all stakeholders in the biomass energy supply chain.

Keywords: Green business model, Biomass, Sustainability Balanced Scorecard, Social Return on Investment

1. INTRODUCTION

The growth of the economy focuses on highly consumption-oriented production which in turn relies on limited natural resources and cannot generate a new replacement or may require a longer period of time to build up a replacement such as petroleum, coal, and natural gas which are unclean raw materials for energy production**.** The rising raw material costs and the use of natural resources in the international market cause higher production costs for the industry, as well as climate change, and increase waste, wastewater, and air pollution**.**

The concept of green economy has been presented by the United Nations Environment Programme to adjust the current capitalist economic system towards more sustainable economic system**.** An economic system enhances quality of life and social justice. At the same time, it can reduce the environmental risk and the problem of resource scarcity in accordance with business outcomes in the economic, social, and environmental dimensions based on the Triple Bottom Line concept [1]. The concept of "Green Business" emerged at the end of the 20th century in the wake of the ever-increasing public concern about the sustainability of economic development as an ideology and practice for business unit in the economic system**.** However, green business practices are still not universally embraced and applied by different business entities around the world [2].

Electricity from non-renewable energy comes from natural resources such as fossil fuels**.** However, burning fossil fuels is harmful to the environment**.** When fossil fuels are combusted **(**heated**),** they release carbon dioxide **(**CO_2**)** into the atmosphere**.** Carbon dioxide is a gas that keeps heat in the earth's atmosphere, a process called the "greenhouse effect**.**" This causes temperatures to rise faster than organisms can acclimate [3] .

Renewable energy such as solar, hydropower, wind power, biogas, waste, and biomass are related to people's well-being and the country's development**.** In the past, the Thai government was the only producer and manager of electricity production from non-renewable energy. But the undertaking was not

sufficient to cover the needs of communities in such a developing country like Thailand that was growing rapidly and affected the investment of power supply as it required large budget each year. Therefore, to reduce the burden on government investment in the construction of the power plant to meet the demand and to stabilize the country's electrical system, in 1994 Electricity Generating Authority of Thailand encouraged private sector participation in power generation business through purchasing of electricity from cogeneration power plants of the Independent Power Producers that used waste or residues in the agricultural sector (Biomass) as feedstock to produce electricity and heat. Heat left over from the manufacturing process could be used to produce electricity for sale to a transmission line to promote generation efficiency and public investment in the production and distribution of electricity. Private power producers therefore had a role as business unit in Thailand's electricity production. Subsequently in 1998, the National Energy Policy Council approved Very Small Power Producers (VSPP) (capacity not larger than 10 MW). More VSPPs were set up in remote areas to participate in the production of electricity from renewable energy in accordance with Thailand Power Development Plan 2015-2036 with the focus on (1) Energy security, to supply energy in response to the energy demand which was consistent with the rate of economic growth, the rate of population growth, and the growth of urban areas, as well as the diversification of energy to appropriate resources. (2) Economy, taking into account the reasonable energy costs without posing obstacle to the country's long-term economic and social development. The structure of fuel prices was reformed in line with costs and tax burden reasonable to level up national energy utilization performance with the promotion of energy efficiency. (3) Ecology, with increased domestic renewable energy production and energy production with high performance technologies to reduce the impact on environment and community [4] .

In 2017, biomass could produce electricity to Thailand about 651.1 MW, highest of all renewable energy sources [5]. Although Thailand is an agricultural country and is appropriate for biomass energy, electricity production from biomass may cause pollution impacting the environment, public health, and resistance from the affected citizens, if there is no proper management. Another factor is the provision of law that stipulates VSPP to conduct an Initial Environmental Examination (IEE) instead of Environmental Impact Assessment (EIA) that is a full assessment of the effects of the project on the environment which is a more detailed and comprehensive study of environmental impact than IEE [6]. In Thailand the biomass power plant with the generating capacity of 9.9 MW (<10MW) is not required to conduct the EIA, only conduct the IEE. Therefore, entrepreneurs can avoid conducting the environmental impact assessment by constructing the VSPP with lower investment in pollution management and technology than small power producers (SPP) (>10MW capacity). Subsequently, VSPP tend to pollute more than SPP. Therefore, VSPP must ensure that they carry out their business responsibly.

Under the green business topics, there are several education issues about green business practices in consumer products and services such as the ecolabeling (also known as green or environmental labeling, or green branding) [7], green behavior "4Rs" – reduction, reuse, recycling, and recovery [8], increased revenue from green business [9], etc. Therefore, the researchers anticipated that the concept of green business constructed from Sustainability Balanced Scorecard (SBSC) concept [10] and Biomass Supply Chain for Energy Production concept [11] could be deployed with public utility business such as biomass very small power producers electricity production. Consequently, biomass very small power (BVSPP) could generate profit coupled with responsibility for the environment and society.

2. OBJECTIVE

The objective of this study was to construct the Green Business Model of Biomass Very Small Power Producers which could bring sustainable benefit to BVSPP by-product from cost reduction along with reducing environmental impact and establishing good relation to society and communities surrounding the power plant.

This model was suitable for adoption by BVSPP which would assist in develop the green business potential of the biomass power plants as it was an economic approach that promoted sustainable development in all sectors of the country, including economy, society, and environment.

3. METHODOLOGY

This study was qualitative research. Secondary data was collected through books, documents, information media, and research works relevant to green business, biomass energy, stakeholders, and SBSC to formulate the (draft) of the Green Business Model of Biomass Very Small Power Producers conceptual framework.

Then, the Green Business Model of Biomass Very Small Power Producers was constructed by semi-structured interviews relevant to indicator criteria of SBSC concept to investigate the appropriateness of the issues in the (draft) of the Green Business Model of Biomass Very Small Power Producers conceptual framework, as well as the appropriateness of the content and language. Total of semi-structured interviews were conducted with 18 stakeholders each

from biomass supply chain including 3 business entrepreneurs of BVSPP, 3 feedstock producers/suppliers, 3 feedstock transport companies, 3 community leaders, 3 government officers and 3 non-governmental organizations (NGOs) as shown in Table 1.

Table 1 Key Informants of the Study

Types of stakeholders	Participants
Business entrepreneurs	1-3 BVSPP entrepreneurs
Feedstock producers/ suppliers	1-3 Farmers as biomass feedstock suppliers
Feedstock transport	1-3 Private companies providing transport services
Community	1-3 Community leaders living within the radius of 3 kms from the power plant
Government	1 Ministry of Industry officer 1 Local administration organization officer 1 Electricity Generating Authority of Thailand (EGAT) officer
NGOs	1 NGO 2 Academics

The (draft) of Green Business Model of Biomass Very Small Power Producers conceptual framework investigated and suggested by 18 interviewed persons usage of main structure to create the Green Business model of Biomass Very Small Power Producers in accordance with the context of SBSC concept.

4. GREEN BUSINESS MODEL OF BIOMASS VERY SMALL POWER PRODUCERS

This research was the study of the green business model of BVSPP by using the green business concept taking into account the economic, social, and environmental contexts as foundation, and the conceptual framework of SBSC [10,12,12–15] developed from the balanced scorecard concept [16]. The objective was to apply it to the business context of biomass power generation covering the stakeholders in the overall process in line with the concept of biomass supply chain Management [11,17–20] consisting of the following contexts in line with the green economy concept. The researchers formulated the green business model of Biomass Very Small Power Producers conceptual framework as shown in Figure 1.

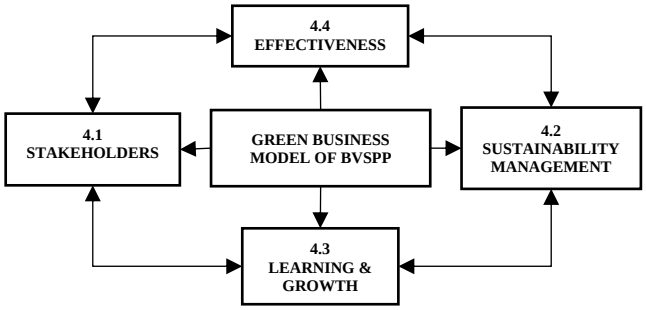

Fig. 1 Green Business Model of Biomass Very Small Power Producers

The green business model of Biomass Very Small Power Producers presented the four key aspects similar to four key perspectives of the SBSC consisting of: Learning and growth aspect, Sustainability management aspect, Stakeholder aspect, and Effectiveness aspect. Each aspect is detailed as follows:

4.1 STAKEHOLDERS

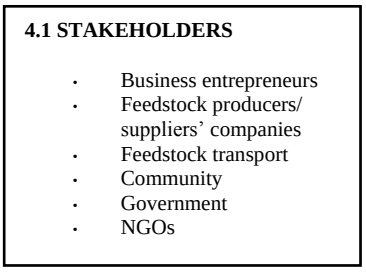

Fig. 2 STAKEHOLDERS aspect in Green Business Model of Biomass Very Small Power Producers

The conceptual framework of stakeholders aspect was investigated by 18 key informants from stakeholders of biomass supply chain. It focused on specifying type of stakeholders and reflected on how the business was creating stakeholders' value through its strategy and actions. In other words, it was the perspective on how to specify the stakeholders in the concept of Biomass Supply Chain [11,17,18,18–20]. The conceptual framework of stakeholders aspect was developed from the customer perspective in line with the SBSC concept.

To specify the target groups of stakeholders in green business model of biomass energy power plant, business should use the stakeholder's guideline framework developed from the evaluation of key informants to define type of stakeholders relevant to own operation of biomass power plant as shown in Table 2.

Table 2 Guideline Framework of Stakeholders

Types of stakeholders	Stakeholders
Business entrepreneurs	- BVSPP entrepreneurs - Shareholders - Officials relevant to process of biomass power generation
Feedstock producers/ suppliers	- Farmers as biomass feedstock suppliers - Communities as biomass feedstock suppliers
Feedstock transport	Feedstock logistics includes all of the unit operations necessary to move biomass feedstock from the land to the bio refinery and to ensure that the delivered feedstock meets the specifications of the bio refinery conversion process [21]. - Private companies providing transport services
Community	- Community leaders - Locals living within the radius of 3 kms from the power plant
Government	Responsible officials from: - Provincial Industry Office - Department of Industrial Works - Ministry of Industry - Office of Energy Regulatory Commission - Local administration organization - Metropolitan Electricity Authority, Provincial Electricity Authority, Electricity Generating Authority of Thailand
NGOs	- NGOs - Academics

4.2 SUSTAINABILITY MANAGEMENT

4.2 SUSTAINABILITY MANAGEMENT

Variable Costs

Economic management
- Feedstock provision
- Feedstock transport management
- Biomass feedstock storage
- Shareholder management
- Personnel management
- Quality control of power generation

Social management
- Participation of personnel and community
- Employment of local labor force
- CSR
- Agreement between BVSPP and community
- Community development fund in area surrounding power plant

Environmental management
- Environmental impact management in Biomass Supply Chain (air, energy, water, eco system, noise, waste)
- Raise environmental awareness to personnel
- Comply with law on power plant operation

Fig. 3 SUSTAINABILITY MANAGEMENT aspect in Green Business Model of Biomass Very Small Power Producers

Sustainability management aspect based on the evaluation of business entrepreneurs' interviews was the internal business process perspective that indicated business processes in key internal dimensions. It was the perspective of the management process of BVSPP in the economic, social, and environmental contexts. Most of the business entrepreneurs and officers commented that each activity in Sustainability management aspect including Economic management, Social management, and Environmental management was the variable cost of the investment in power generation. Sustainability management aspect was developed from the internal process perspective in line with the SBSC concept consisting of:

1. Economic management

- Feedstock provision: Rigorously inspect the quality of biomass bought in each lot in accordance with the standards of quality control of feedstock (Certification of testing of biomass composition).

- Feedstock transport management: Process to manage removal and storage of biomass feedstock during transport from feedstock suppliers to power plant.

- Biomass feedstock storage: Systematic feedstock storage management worth the investment, quality control of storage, prevention, reduced loss of operation for minimum operating costs and maximum use of storage space for biomass feedstock (depending on distance and seasons).

- Shareholder management: Safeguard and distribute return to shareholders to prevent conflict of themselves, partners, and business.

- Quality control of power generation: Control the process of power generation with stability (Output of electrical units was consistent depending on quality of feedstock such as humidity causing brownout).

2. Social management

- Community participation: Provide opportunity for the public to determine their own needs for resouce management, decision-making, and control of various activities related to community.

- Employment of local labor force: Employment of local people as part of business operation of BVSPP.

- Social responsibility: Organize Corporate Social Responsibility (CSR) and environmental activities both in and outside the organization towards sustainable development such as donation for social assistance.

- Agreement between BVSPP and community (Commitment): Contribute to the fund according to installation capacity of power plant, grant scholarship to community, improve basic infrastructure to community such as roads, temples, clinics, restrooms.

3. Environmental management

- Management of environmental impact from power generation processes (air, water, eco system, noise, waste): Determine measures to reduce environmental impacts from power generation processes such as dust filter system from combustion chamber, management of impact on water system, management of eco system around biomass power plant, management of noise pollution, "Eco efficiency" strategies or 4Rs such as disposal or use of waste from combustion.

- Raise environmental awareness: Campaign to raise awareness to personnel in power plant to learn about environment, as well as raising awareness of the environmental problems at national and global levels.

- Compliance with law relevant to operation of power plant: Implementation of policy, targets, rules and regulations, including law, stipulations, standards of environment and safety.

4.3 LEARNING & GROWTH

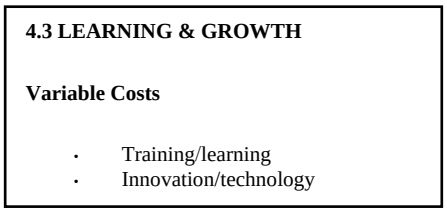

Fig. 4 LEARNING & GROWTH aspect in Green Business Model of Biomass Very Small Power Producers

Based on information from business entrepreneurs' interview, learning and growth aspect was measures of how well the business prepared to meet the challenges of the future obstacles through leveraging its organizational and human assets. It was BVSPP's learning and growth strategy by which each activity was the variable cost of the investment in power generation covering the impact on the stakeholders of the overall biomass supply chain management consisting of:

- Training / learning: Process of systematic learning management to create or enhance knowledge, skills, ability, and attitude that would improve the efficiency of operation, including raising awareness and campaigning for environment.

- Innovation / technology: Technology usage to increase efficiency in working system, reduce Input (feedstock) and increase Output (electric current) and pollution disposal system.

4.4 EFFECTIVENESS

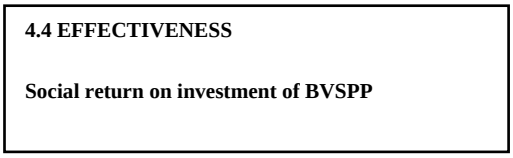

Fig. 5 EFFECTIVENESS aspect in Green Business Model of Biomass Very Small Power Producers

Based on information from stakeholders' interview, effectiveness aspect of Biomass Very Small Power Producers production should show the stakeholders' interests and the link between strategic objectives and financial, social, and environmental impacts. It was the perspective that BVSPP executives could inspect the success of BVSPP in economic, social, and environmental fields. Measure the results by using the processing tools from the social return on investment (SROI) analysis [22] existing in cost–benefit analysis. Which was a methodology for calculating SROI to explain that, for every investment of every single baht, the amount of money the society would receive in return (effectiveness) from the use of biomass to generate power. The analysis and the division of SROI covered economic, social, and environmental dimensions, both in monetary and non-monetary terms, in line with the sustainable development guideline [23]. The SROI could be calculated as follows:

SROI of BVSPP =

$$\frac{\text{Benefits received by BVSPP from investment in power generation}}{\text{Cost of investments in biomass power generation}}$$

The information from key informants revealed that the investment costs in biomass power generation consisted of the following: Fixed costs were the total costs that did not change according to the amount of power generation during the time of operation (machinery useful life) including equipment, machinery, construction, land, feedstock, etc. as shown in Table 3.

Table 3 Guideline Framework of Fixed Costs

Fixed costs	Value
Project development	Baht/Useful Life
Land value	Baht/Useful Life
Equipment, machinery	(Cost Price of Asset – Scrap Value) / Useful Life
Construction (basic infrastructure)	Baht/Useful Life
Commissioning	Baht/Useful Life
Lending interest all through the project	Baht /Useful Life

Variable Costs were the total costs that changed in proportion to the change in the level of activity or amount of power generation which included the following: sustainability management costs and learning & growth costs as shown in Table 4.

Table 4 Guideline Framework of Variable Costs

Variable costs	Value
Fuel	Baht/year
Labor	Baht/year
Feedstock storage	Baht/year
Utilities	Baht/year
Machinery repair and maintenance	Baht/year
Feedstock transportation	Baht/year
Personnel training	Baht/year
Contribution to community development fund in the area around power plant	Baht/year

The information of the value added received by BVSPP from investment in power generation consisted of the following: economic, social, and environmental benefits as shown in Table 5.

Table 5 Guideline Framework of Benefits

Economic benefits	Value
Income from sale of electricity	Baht/year
Reduce import value of petroleum	Baht/year
Social benefits	**Value**
Employment of local labor force	Baht/year
Community income from feedstock of biomass fuel	Baht/year
Feedstock transport in community	Baht/year
CSR activities	Baht/year
Community income from community development fund in the area around the power plant	Baht/year
Environmental benefits	**Value**
Reduced amount of greenhouse gas emission from biomass fuel usage instead of fossil fuel	Baht/year (value of carbon credit from the reduced CO_2)

The effectiveness aspect of Biomass Very Small Power Producers production analysis was then conducted on the SROI Ratio assigning a monetary value to investment costs and benefits (inputs and outcomes), using that assignation to calculate a ratio. For example, if the SROI Ratio is 5:1, which means that every baht allocated on investment costs will generate benefit worth five baht.

CONCLUSION

Without establishment of effective mechanism for sustainable management of the business combine with Economic, environmental and social impacts from biomass power production may pose a risk and conflicts to stakeholders of biomass business sectors in Thailand. Green Business Model of Biomass Very Small Power Producers concept is an effective scheme for Biomass Very Small Power Producers as business strategy and its performance focusing on four specific aspects: Learning and growth aspect, Sustainability management aspect, Stakeholders aspect, and Effectiveness aspect. Each aspect has shown a strong and positive link between successful implementation of a business strategy of Biomass Very Small Power Producers with social and environmental strategies.

Green Business Model of Biomass Very Small Power Producers is innovative and required at a specified time for sustainable operations of biomass power plants in Thailand. It directly leads to sustainable management and benefit in term of social return on investment for all of the stakeholders in biomass energy supply chain (Economic benefits), all of which respond to the environment and reduce greenhouse gas emissions, particle pollution and carbon-monoxide emissions (Environmental benefits). That also makes immense and positive contribution to rural economy of Thailand **(**Social benefits) in terms of income and employment to farmers, entrepreneurs at village level, and rural youth. Which also leads to development of other value-added products such as biofuels and establishment of small-scale industries such as biomass briquetting plants.

DIRECT SHEAR STRENGTH OF HEATING AND HYDRATION BENTONITE-SAND MIXTURE SAND

Tomoyoshi Nishimura[1]
[1]Ashikaga University, Japan

ABSTRACT

It is important one of environmental geotechnical problems that relevant researches of thermal-hydration-mechanical-chemical have been progressed for radioactive waste disposal in further deep geological repositories combined highly compacted bentonite. The compacted bentonite engineered barrier is constructed under unsaturated condition which is as liner. Many couple models and investigation at in-site were reported that these results really have contributed to establish certain interpretation of engineered barriers system with detail. The model gradually solve, and reproduce comparison with measurement data on account of complex experimental test associated to thermal-hydration-mechanical. This study focused on shear strength of bentonite-sand mixture, which treated by thermal-hydration efforts as one of great significance like a predicted environmental problems to engineered barrier. Shear strength was measured using direct shear apparatus that constant vertical stress was applied at remaining of constant horizontal displacement speed. Prepared all samples were mixture Na-type bentonite and silica sand having uniformity grain size distribution. Compacted sample had a dry density of 1.600 g/cm^3. Also, heating control was supplied under 80 degrees as thermal effort in the heating oven. Heating flow was isotropic condition and soil moisture decrease, became to a like dry condition. The paper summarized on direct shear strength, influences of thermal-hydration was described certainly.

Keywords: Bentonite, Thermal effort, Suction, Direct shear strength, SWCC

INTRODUCTION

During long-term periods operation radioactive disposal waste repository at large deep underground, bentonite as natural swelling material apply one composed of barrier system [1][2]. Many investigation reports were published, mentioned in widely world and could commonly take data base from various research facilities. These results were based on laboratory, large scale testing at underground site and developed mathematical simulation model analysis [3]. The constitutive models was quiet difference with classical soil mechanical theory on saturated clay soil and consist of hydration, thermal effort and chemical effort. THMC analysis models [4][5] have been significant developed according to compare between experimental results in laboratory and underground site investigation works and to determine high quality parameters associate to predict barrier system composed by bentonite remain processing development of models.

PURPOSE OF THIS STUDY

This study conducted out direct shear test at constant vertical stress which used compacted bentonite-sand mixture sample subjected to heating process. Also other samples were applied hydration effort due to controlling relative humidity using vapor pressure technique. It was found out the influence of thermal effort on direct shear strength including reduction of mount of soil moisture and in addition various horizontal displacement speeds were focused other factors to strength of compacted bentonite-sand mixture.

SOIL MATERIALS AND APPARATUS

Sodium bentonite （Kunigel V1）taken in Japan was used for direct shear test and chemical component SiO_2 of the material occupied 62 %. The bentonite has been widely used for investigation of mechanical properties of high level radioactive disposal barrier system in Japan. Often, the material specimen was employed as one of reference materials and had comparison to other swelling clay materials in the outside. A sand was mixture into the bentonite which uniformity grain size distribution was indicated from grain size test and evaluated to classify as siliceous sand. Water supply was performed to material and was regulated to water content of 5.9 %.

Previously, soil-water characteristic curve [6] was described at high suction ranges which was defined relationship between suction and water content in Fig.1. The SWCC consisted various temperature until suction was 296 MPa. Range of temperature was from 20 degrees and 80 degrees that influence of temperature was further slight. Bentonite with sand mixture was statically compacted in the shear box.

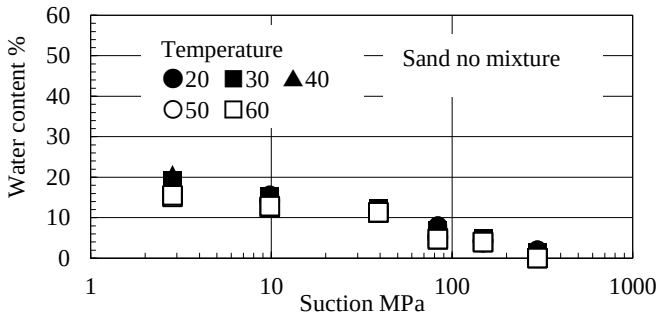

Fig. 1 SWCC with various temperatures.

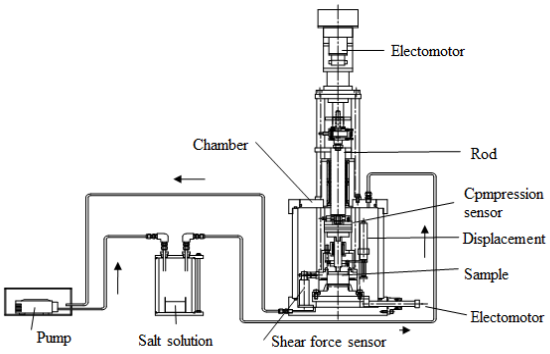

Fig. 2(a) Illustration of direct shear apparatus.

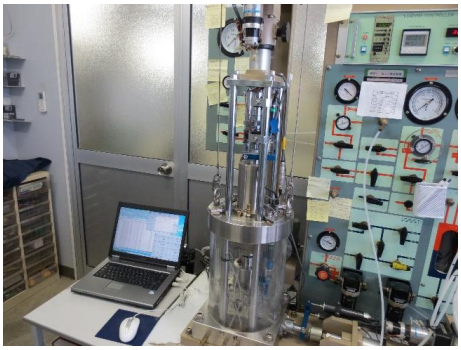

Fig. 2(b) Direct shear test apparatus

The specimen corresponding suction of 105 MPa had a dry density of 1.600 g/cm^3 which a diameter of 6.00 cm and a height of 2.50 cm.

This testing program used a modified direct shear apparatus as shown in Fig.2(a) (b). The modified direct shear apparatus was possible to maintain constant vertical stress and suction which was developed to evaluate unsaturated soil behavior with suction stress. Shear box was placed in the cell chamber and shear forces induced by horizontal moving of lower box was measured during test. Vertical stress was produced due to control pressure cylinder installed at outside cell chamber.

This study considered how magnitude of pore pressure in specimen under increasing of temperature

Fig. 3 Steel mould for measurement of pore pressure under 80 degrees.

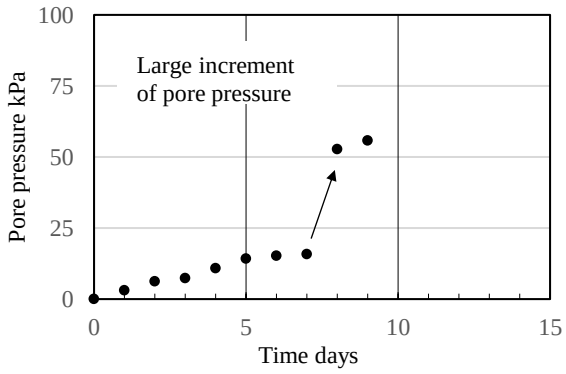

Fig. 4 Increment of pore pressure due to isotropic heating under 80 degrees.

and conducted out measurement of pore pressure specimen installed into stiffness steal mould. The steal mould was covered by two steal plate as shown in Fig.3 and specimen was closed completely.

TESTING CONDITIONS

This testing program consist of various horizontal displacement speed, difference vertical stress, thermal effort on direct shear test. Controlled horizontal displacement speed had a range from 0.0005 mm per min to 0.5 mm per min that it was further difference testing times. Measured vertical stresses were both 100 kPa and 200 kPa. Influence of thermal effort was consider under both temperatures between 20 degrees and 80 degrees. When 80 degrees was controlled, all specimen with shear box were placed in large oven chamber.

PRESSURE IN SAMPLE DUE TO HEATING

It is knowledge that heating loading developed pore pressure in void structure and this study investigated changing of pore pressure as shown in Fig.3. Obtained pressures were averaged using results both upper portion and lower portion that were described as shown in Fig.4 At beginning of heating for approaching to 80 degrees,

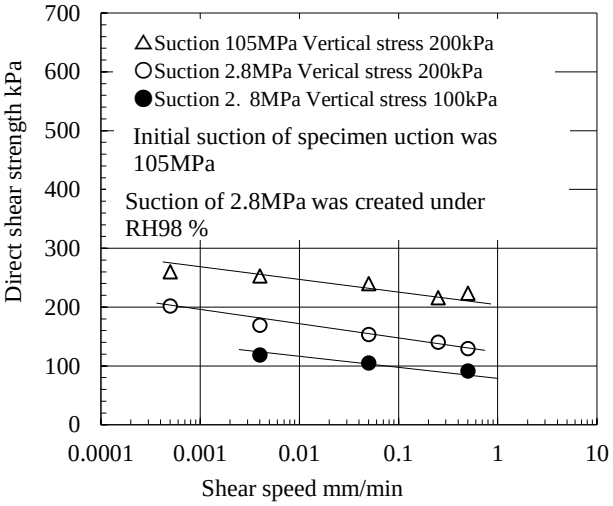

Fig. 5 Influence of some factor on direct shear strength.

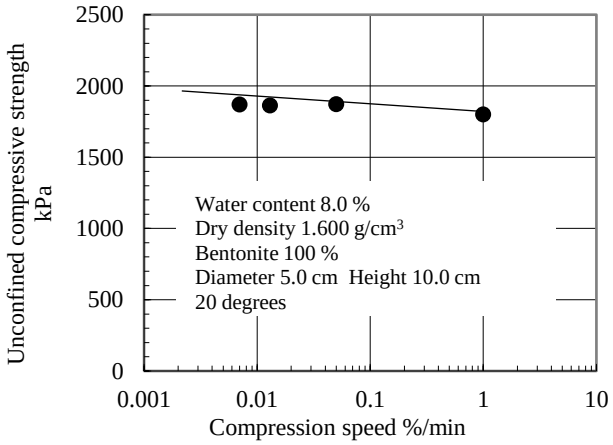

Fig. 6 Influence of compression speed on unconfined compressive strength.

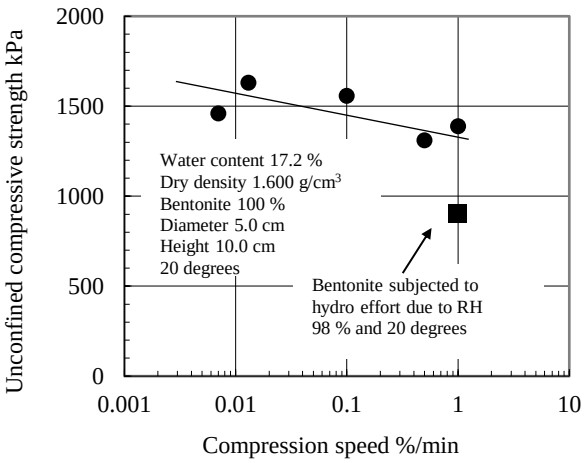

Fig. 7 Influence of compression speed on unconfined compressive strength.

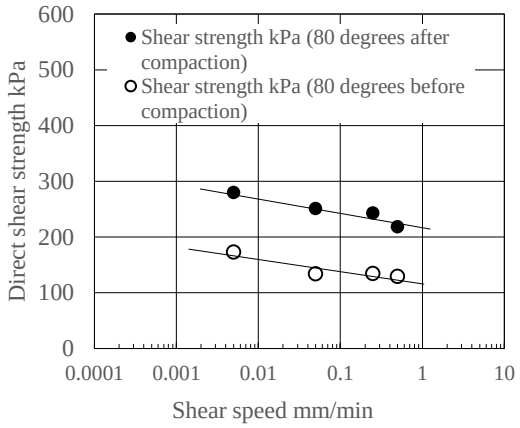

Fig. 8 Direct shear strength subjected to thermal effort.

pore pressure was smoothly produced, increased linearly with days. Large increment was observed beyond 7 days from 15.7 kPa and the pressure improved to over 50 kPa due to jumping growing. Interpretation and accumulation of experimental data sets regard to changing of pore pressure have been required to confirm mathematical models correctly.

SHEAR STRENGTH AT 20 DEGREES

Measurement of direct shear strength of compacted bentonite was conducted with two difference vertical stress such as 100 kPa and 200 kPa. Relationship between horizontal displacement speed and strength was mentioned as shown in Fig.5. Shear strength increased with high vertical stress that following to failure envelope line. In addition, it was of interesting phenomena that direct shear strength decreased according to increase horizontal displacement. Thus results were indicated regardless of both vertical stress. Unconfined compressive strength that reduction of strength closely related increasing of compression speed as shown in Figs.6 and 7.

Also, suction effort was observed that two difference suction (i.e. 105 MPa and 2.8 MPa) were applied to specimen and conducted out direct shear test. Reduction of strength due to decreasing of suction was further clear.

DISCUSSION ON THEARMAL EFFORT

Compacted specimens were placed into oven chamber, which was remained at temperature of 80 degrees. The specimen was with shear box and seven days were prepared for applying heating at least.

Beyond heating, the specimen within shear box was established into direct shear apparatus and specimen was equilibrium with laboratory room temperature (i.e. 20 degrees). Subsequently, applying of vertical stress of 200 kPa was processed and direct shear strength was measured at various horizontal displacement speeds. Also, powder material was prepared for compaction specimen which applied heating effort under 80 degrees and water content at equilibrium was 0.21 %. The powder material was statically compaction in the shear box according to dry density of 1.600 g/cm^3. Direct shear strength was measured similar to previous process. Two difference specimen described the difference strength as shown in Fig.8 and it was found that strength was lower than that of compacted specimen under 5.9 % water content subjected to heating. Even both water content and dry density were same, reduction of shear strength was observed. In addition, it was evidenced that shear speed affected to change of shear strength.

CONCLUSIONS

This study consider the influence of thermal effort through constant vertical stress direct shear test and applied temperature was up to 80 degrees. Also, results of direct shear strength with various horizontal displacement speed described significant properties associated to the influence of strain speed on strength regardless of thermal effort or no thermal effort.

Direct shear strength of compacted bentonite-sand mixture increased with vertical stress and indicated the increasing of strength with growing of horizontal displacement speed. Thus like an experimental tendency, it was found similar to unconfined compressive strength of compacted bentonite with various compression speed.

Also, tow difference specimens were prepared in thermal effort and lower strengths were demonstrated comparison with compacted specimen subjected to heating action which compacted using powder sample subjected to heating action.
